Walking the Hypercube
September 4, 2015

**Theorem 1.** Any hypercube of dimension $n \geq 2$ has a Hamiltonian cycle.

**Proof by regular induction, standard base case.** We will prove this by induction.

**Base case:** The 2-dimensional cube, shown here:

![2-dimensional cube](image)

has four edges connected in a cycle; this is itself the Hamiltonian cycle.

**Inductive step:** We will assume that an $n$-dimensional hypercube has a Hamiltonian cycle, say $v_1, \ldots, v_{2^n}$. The $n+1$-dimensional hypercube $C_{n+1}$ is formed from two $n$-dimensional hypercubes, say $C_n$ with vertices $v_i$ and $D_n$ with vertices $w_i$ respectively, for $i = 1, \ldots, 2^n$. Then to the union of $C_n$ and $D_n$, we add edges connecting $v_i$ to $w_i$ for each $i$, to form the $n+1$-dimensional hypercube $C_{n+1}$. The case of a 3D cube formed from two squares is shown here:

![3D cube](image)

Now, I claim that the cycle $v_1, \ldots, v_{2^n}, w_{2^n}, w_{2^n-1}, \ldots, w_1$ is a Hamiltonian cycle. This is shown in the diagram above. We must check that all vertices appear and no vertices are repeated (this is immediate), and also that every vertex is adjacent to the previous one. For most edges, the edges are contained in either $C_n$ or $D_n$ and this follows from the inductive hypothesis. The only edges that are new are joining the pairs $(v_{2^n}, w_{2^n})$ and $(w_1, v_1)$. But these exist from the construction of $C_{n+1}$. Hence this is a Hamiltonian cycle and we are done. $\square$
