Finally we'll realize our longterm goal of proving:

The Fundamental Theorem of Arithmetic Every integer > 1 can be written as a product of primes in a unique way.

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

First we generalize **Euclid's Lemma** from 2 to *n* factors.

#### Lemma

Let  $n \in \mathbb{N}$ ,  $a_1, \ldots, a_n \in \mathbb{Z}$ , p prime. If  $p|a_1 \cdots a_n$ , then  $p|a_i$  for some  $i \in \{1, \ldots, n\}$ .

### Proof (by induction on *n*)

**Basis step,** n = 1:  $p|a_1$  and the statement is true.

Induction hypothesis: For a fixed k ∈ N, if p|a<sub>1</sub> ··· a<sub>k</sub>, then p|a<sub>i</sub> for some i ∈ {1, ..., k}.

▶ Induction step: Show the statement follows for n = k + 1. Assume  $p|\underbrace{a_1 \cdots a_k}_{k+1} a_{k+1}$ .

By Euclid's Lemma, p|b or  $p|a_{k+1}$ .

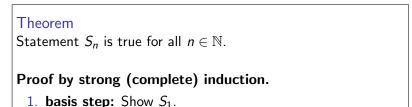

▶ If p|b, then  $p|a_i$  for some  $i \in \{1, ..., k\}$  by the induction assumption.

Else  $p|a_{k+1}$ .

In any case  $p|a_1$  or  $p|a_2$  or  $\dots p|a_k$  or  $p|a_{k+1}$ . The induction step is proved and so is the Lemma.

If induction is not strong enough for you any more ...

2. inductive step: Show  $S_1 \wedge \cdots \wedge S_k \Rightarrow S_{k+1}$  for any  $k \in \mathbb{N}$ .

The only difference to usual induction is that you are allowed to use the

• induction assumption: all  $S_1, \ldots, S_k$  hold

for proving the induction step.

#### Example

Which postage values can be obtained with stamps for \$3 and \$7? Exactly the values of the form

n = 3x + 7y for  $x, y \in \mathbb{N}_0$ 

- **Base cases.** *n* = 3, 6, 7, 9, 10, 12, 13, 14, . . . can be obtained.
- ► Conjecture. All n ≥ 12 can be obtained. We prove this conjecture by strong induction using the base cases above.
- ► Assumption for strong induction. All numbers between 12 and some fixed k ≥ 14 can be obtained.
- Induction step. Show k + 1 can be obtained.
  k 2 is ≥ 12 and can be obtained by induction assumption.
  So k + 1 = (k 2) + 3 can.

**Note.** To get the statement for k + 1, it's no use that we have it for k. Hence we need **strong induction**.

#### Fundamental Theorem of Arithmetic.

1. Every integer n > 1 has a factorization into primes

Proof of 1. by strong induction on n.  $p_{\pm} p_1 p_2 \cdots p_k$ .

- **Basis step:** n = 2 is prime (product of a single prime).
- Induction assumption: For fixed n ∈ N all numbers ≤ n are products of primes.
- Inductive step: Show n + 1 is a product of primes.
  Case, n + 1 prime: n + 1 is the product of a single prime.
  Case, n + 1 not prime: Then n + 1 = ab for some 1 < a, b < n + 1. By the (strong) induction assumption</li>

$$a = p_1 \cdots p_k, \qquad b = q_1 \cdots q_\ell$$

for some primes  $p_1, \ldots, p_k, q_1, \ldots, q_\ell$ . Now  $n + 1 = p_1 \cdots p_k q_1 \cdots q_\ell$  is also a product of primes.  $\Box$ 

Fundamental Theorem of Arithmetic.

1. Every integer n > 1 has a factorization into primes

 $n=p_1p_2\cdots p_k.$ 

2. This prime factorization of *n* is unique up to ordering. That is, if

$$n = p_1 p_2 \cdots p_k = q_1 q_2 \cdots q_\ell$$

for primes  $p_1, \ldots, p_k, q_1, \ldots, q_\ell$ , then  $k = \ell$  and  $(p_1, \ldots, p_k)$  is a permutation of  $(q_1, \ldots, q_k)$ .

#### Example

$$60 = 2 \cdot 2 \cdot 3 \cdot 5 = 2 \cdot 3 \cdot 5 \cdot 2$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Same primes, different order.

#### Fundamental Theorem of Arithmetic.

#### 2. If

$$n = p_1 p_2 \cdots p_k = q_1 q_2 \cdots q_\ell$$

for primes  $p_1, \ldots, p_k, q_1, \ldots, q_\ell$ , then  $k = \ell$  and  $(p_1, \ldots, p_k)$  is a permutation of  $(q_1, \ldots, q_k)$ .

### Proof of 2. by minimal counterexample.

Suppose 2. is false. Then there is some counterexample. Since  $\mathbb{N}$  is well-ordered, there must be a minimal (smallest) counterexample *n*. Note n > 2 because 2 can be written as a product of primes in only one way.

#### Proof of 2. continued

Recall n is minimal such that

$$n = p_1 p_2 \cdots p_k = q_1 q_2 \cdots q_\ell$$

for primes  $p_1, \ldots, p_k$  and  $q_1, \ldots, q_\ell$  that are not permutations of each other.

- Since  $p_1|q_1q_2\cdots q_\ell$ , by Euclid's Lemma  $p_1|q_i$  for some *i*.
- Since  $q_i$  is prime,  $p_1 = q_i$ .

Dividing by p<sub>1</sub> yields

$$\frac{n}{p_1}=p_2\cdots p_k=q_1q_2\cdots q_{i-1}q_{i+1}\cdots q_\ell.$$

- ▶  $p_2, \ldots, p_k$  and  $q_1, \ldots, q_{i-1}, q_{i+1}, \ldots, q_\ell$  are **not** permutations of each (else  $p_1, \ldots, p_k$  and  $q_1, \ldots, q_\ell$  would be as well).
- $\frac{n}{p_1}$  is a counterexample for 2. that is smaller than *n*.

But *n* was the smallest counterexample. Contradiction! There is no smallest counterexample (no counterexample at all). Item 2. of the Fundamental Theorem was proved by a special version of a proof by contradiction combined with induction:

**Proof by minimal (smallest) counterexample.** To show that a statement  $S_n$  is true for every  $n \in \mathbb{N}$ :

- **basis step:** Show  $S_1$ .
- Suppose k > 1 is smallest such that S<sub>k</sub> is false. Show that there exists some smaller ℓ < k such that S<sub>ℓ</sub> is false.

# An application of prime factorizations

Find common divisors of

$$\begin{array}{rl} a=&2^2\cdot 3^1\cdot 5^3\\ b=&2^3\cdot 3^0\cdot 5^1\\ &&2^2\cdot 3^0\cdot 5^1 \end{array} \text{ divides } a,b, \text{ in fact is } \gcd(a,b) \end{array}$$

Let  $p_1 = 2, p_2 = 3, p_3, ...$  be the list of all primes. Fundamental Theorem of Arithmetic: every  $a \in \mathbb{N}$  has a unique form

$$a = p_1^{e_1} \cdot p_2^{e_2} \cdot p_3^{e_3} \dots$$

with almost all exponents  $e_i \in \mathbb{N}_0$  equal to 0.

#### Lemma

Let  $a = \prod_{i \in \mathbb{N}} p_i^{e_i}$ ,  $b = \prod_{i \in \mathbb{N}} p_i^{f_i}$  with  $e_i$ ,  $f_i \in \mathbb{N}_0$  for all  $i \in \mathbb{N}$ . Then 1.  $gcd(a, b) = \prod_{i \in \mathbb{N}} p_i^{min(e_i, f_i)}$ , 2.  $lcm(a, b) = \prod_{i \in \mathbb{N}} p_i^{max(e_i, f_i)}$ , 3.  $gcd(a, b) \cdot lcm(a, b) = ab$ . Proof of 1. Clearly  $\prod_{i \in \mathbb{N}} p_i^{\min(e_i, f_i)}$  divides  $a = \prod_{i \in \mathbb{N}} p_i^{e_i}$  and  $b = \prod_{i \in \mathbb{N}} p_i^{f_i}$ . We show that it is the **greatest** common divisor.

- Assume  $d = \prod_{i \in \mathbb{N}} p_i^{g_i}$  is some divisor of *a* and *b*.
- ▶ Let  $i \in \mathbb{N}$  and  $g_i \ge 1$ . Note that  $p_i$  does not divide  $\frac{a}{p_i^{e_i}}$  by the Fundamental Theorem of Arithmetic.

• Then 
$$p_i^{g_i}$$
 cannot divide  $\frac{a}{p_i^{e_i}}$ 

- Since p<sup>g<sub>i</sub></sup><sub>i</sub>|a, we then get p<sup>g<sub>i</sub></sup><sub>i</sub>|p<sup>e<sub>i</sub></sup><sub>i</sub> and g<sub>i</sub> ≤ e<sub>i</sub>. Note that this holds for g<sub>i</sub> = 0 as well.
- Similarly  $g_i \leq f_i$ .
- Hence  $g_i \leq \min(e_i, f_i)$ .

Hence for any common divisor d of a and b we have

$$d \leq \prod_{i \in \mathbb{N}} p_i^{\min(e_i, f_i)}$$

and the latter is the gcd(a, b).
