Date $\qquad$

The final copy of this thesis has been examined by the signatories, and we find that both the content and the form meet acceptable presentation standards of scholarly work in the above mentioned discipline.

#### Abstract

Havasi, Krisztián (Ph.D., Mathematics, Department of Mathematics) Geometric Realization of Strata in the Boundary of the Intermediate Jacobian Locus Thesis directed by Associate Professor Sebastian Casalaina-Martin

In this thesis we describe intermediate Jacobians of threefolds obtained from singular cubic threefolds. By this we mean two things. First, we describe the intermediate Jacobian of a desingularization of a cubic threefold with isolated singularities. Second, we describe limits of intermediate Jacobians of smooth cubic threefolds, as the family of cubic threefolds acquires isolated singularities. In regards to the first question, generalizing a result of Clemens-Griffiths we show specifically that the intermediate Jacobian of a distinguished desingularization of a cubic threefold with a single singularity of type $A_{3}$ is the Jacobian of the normalization of an associated complete intersection curve in $\mathbb{P}^{3}$, the so called $(2,3)$-curve. In regards to degenerations, we describe how the limit intermediate Jacobian, under certain conditions, can be described as a semi-abelian variety as the extension of a torus by the finite quotient of the product of Jacobians of curves, where one of the curves is the normalization of the $(2,3)$-curve associated to the cubic threefold and a choice of singularity, and the other curves are so-called tails arising from stable reduction of plane curve singularities.

## ACKNOWLEDGEMENTS

I give many thanks to my advisor Professor Sebastian Casalaina-Martin for all his help throughout these years. I would also like to thank the Dance Department at CU Boulder, its wonderful faculty and dancers without whom this thesis would never have seen the light of day.

## Chapter 1

## Introduction

Cubic threefolds (smooth cubic hypersurfaces in $\mathbb{P}^{4}$ ) have played an important role in the development of algebraic geometry. By the global Torelli theorem for cubic threefolds, a well known result of Clemens and Griffiths [CG72], smooth cubic threefolds can be recovered from their principally polarized intermediate Jacobians, just like smooth curves can be recovered from their principally polarized Jacobians. In their celebrated paper [CG72], using the intermediate Jacobian as a tool of study, Clemens and Griffiths also showed that smooth cubic threefolds are not rational. Since these results the intermediate Jacobian has played a central role in the study of smooth cubic threefolds. Much attention has also been paid to the degeneration of the intermediate Jacobian as the cubic threefold becomes singular. It turns out that intermediate Jacobians of smooth cubic threefolds are in fact Prym varieties [Mum74], therefore one way to study degenerations of intermediate Jacobians is through degenerations of Prym varieties. Our goal is to compute the degenerate intermediate Jacobian as a degenerate Prym variety for several cubic threefolds with various singularities. Another interesting question is that if we have a singular cubic threefold, how can we describe the intermediate Jacobian of a desingularization? We answer this question in the cases of a cubic threefold with a single singular point of type either $A_{1}, A_{2}$ or $A_{3}$ (the $A_{1}$ case is due to Clemens and Griffiths, and the $A_{2}$ case essentially follows immediately from that argument).

If $X$ is a cubic threefold with isolated singularities only and with a distinguished double point $P$, we can project from $P$ the lines of $X$ passing through $P$. The projection is then a (2,3)-complete intersection curve $C$ in $\mathbb{P}^{3}$ with the property that the blow-up of $\mathbb{P}^{3}$ along $C$ is isomorphic to the blow-up of $X$ at $P$, and the singularities of $C$ are the same as the singularities of the blow-up of
$X$ at $P$. Thus $C$ is nonsingular if $X$ has an $A_{1}$ or $A_{2}$ singularity at $P$ and no other singularities. To find the intermediate Jacobian of the desingularization of $X$ in this case (i.e. the intermediate Jacobian of the blow-up of $X$ at $P$ ), using that $\mathrm{Bl}_{P} X \cong \mathrm{Bl}_{C} \mathbb{P}^{3}$ we only need to know how the cohomology changes when we blow up a manifold along a smooth submanifold. This is well-known (we review the details in this thesis for completeness), and so we find that the intermediate Jacobian of the desingularization of a cubic threefold with a single $A_{1}$ or $A_{2}$ singularity is the Jacobian of the curve $C$. In the case of a single $A_{3}$ singularity the situation is more complicated, because $C$ is now singular with one node. Using the theory of toric varieties we prove

Theorem 1.0.1. If $X$ is a cubic threefold with a unique singularity, which is of type $A_{3}$, the intermediate Jacobian of the desingularization of $X$ obtained by two successive blow-ups of the singular point, is the Jacobian of the normalization of the associated (2,3)-curve.

Let $L \subset X$ be a sufficiently general line. The planes of $\mathbb{P}^{4}$ containing $L$ can be parameterized by $\mathbb{P}^{2}$. Let $D \subset \mathbb{P}^{2}$ be the discriminant curve belonging to $L$, i.e. the curve whose points represent planes intersecting $X$ in $L$ and two residual lines. Then $D$ has a double cover $\widetilde{D} \rightarrow D$, where points of $\widetilde{D}$ represent the residual lines. The singularities of $D$ are in type-preserving bijection with the singularities of $X$. According to a theorem of Mumford's, in the case of a smooth $X$ the Prym variety of this double cover is isomorphic to the intermediate Jacobian of $X$. Thus in the case of a singular cubic threefold describing the degenerate intermediate Jacobian is the same as describing the degenerate Prym variety of the double cover $\widetilde{D} \rightarrow D$.

A degeneration of a Prym variety is an extension of some quotient of the Prym variety of the desingularization of the double cover $\widetilde{D} \rightarrow D$ (the compact part) with a non-compact torus $\left(\mathbb{C}^{*}\right)^{n}$ :

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{n} \rightarrow P_{\tilde{D} / D} \rightarrow P_{N \tilde{D} / N D} / G \rightarrow 0 \tag{1.0.2}
\end{equation*}
$$

where $N \widetilde{D}$ and $N D$ are desingularizations of $\widetilde{D}$ and $D$, respectively, and $G$ is some finite group, often trivial. We prove that the Prym variety $P_{N \widetilde{D} / N D}$ is isomorphic to the Jacobian of the desingularization of $C$ if $X$ has an $A_{n}$ singularity and $N D$ is non-hyperelliptic, or $X$ has a $D_{4}$ singularity. In fact we have:

Theorem 1.0.3. Let $\mathcal{X} \rightarrow \Delta$ be a general family of cubic threefolds over the unit disk with smooth general fiber and central fiber a cubic threefold $X$ with isolated $A D$ singularities $P_{1}, \ldots, P_{n}$ of types $S_{1}, \ldots, S_{n}$ respectively, with $S_{1}=A_{k}$ for some $1 \leq k \leq 6$, or $S_{1}=D_{4}$. Assume that there is a general line $L \subset X$ so that projection from $L$ yields an irreducible discriminant curve $D \subset \mathbb{P}^{2}$ (which will be the case for instance if $n=1$ ). We further assume that if $P_{1}$ is of type $A_{k}$, the normalization $N D$ is non-hyperelliptic. Then the limit intermediate $\operatorname{Jacobian} I J(X)$ will be a semi-abelian variety

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{r} \rightarrow I J(X) \rightarrow\left(J(N C) \times J T_{1} \times \cdots \times J T_{n}\right) / G \rightarrow 0 \tag{1.0.4}
\end{equation*}
$$

where $N C$ is the normalization of the $(2,3)$-curve $C$ obtained from projection from $P_{1}, T_{i}$ is a so-called tail curve associated to stable reduction of a plane curve singularity of type $S_{i}, G$ is some finite group, and $r=5-g(N C)-\sum_{i=1}^{n} g\left(T_{i}\right)$.

For this theorem, the main contribution of this thesis is to identify the abelian variety $J(N C)$ in the compact part (the remainder of the theorem can be found in [CMGHL15]). This is proven in theorems 3.2.5 and 3.2.14. The special cases where $X$ has a unique singularity, which is of type $A_{1}$ or $A_{2}$ is due to [CM78] and [CML09], respectively. We also note, that we are able to describe the extension data for the semi-abelian variety explicitly, although for brevity, we direct the reader to the body of the thesis.

One of the main goals of this investigation was to identify boundary strata in the closure of the intermediate Jacobian locus in the second Voronoi compactification of $\mathcal{A}_{5}$. In chapter 4 we give explicit descriptions of degenerations of intermediate Jacobians in a number of examples; we describe the semi-abelian varieties. While this is not the complete degeneration data to give a point of the second Voronoi compactification for torus rank 2 or more, this does describe a good amount about how various loci in the boundary can arise geometrically. Nevertheless, we point out that one question we had hoped to answer was what geometric locus of cubic threefolds gives rise to the locus $\mathbf{B}_{22}$ described in [CMGHL15]. Unfortunately, at this point, we have not yet identified this locus.

## Chapter 2

## Intermediate Jacobians of Desingularizations of Cubic Threefolds

### 2.1 Cubic Threefold with Isolated Singularities

Let $X$ be a cubic hypersurface in $\mathbb{P}^{4}$ having a double point at $P=(1: 0: 0: 0: 0)$. Let $\pi$ denote the projection of $\mathbb{P}^{4}$ through the point $P$ onto the hyperplane $\mathbb{P}^{3}$ given by $\left\{x_{0}=0\right\}$. We denote by $C$ the image through $\pi$ of all lines that lie in $X$ and pass through $P$. We start with the following well-known result (see e.g., the references in [CMJL12, §1.2, p. 6]). For completeness, we include a proof here.

Theorem 2.1.1. If $X$ has isolated singularities only, then $C$ is a curve and a complete intersection of type $(2,3)$, and

$$
\begin{equation*}
\mathrm{Bl}_{C} \mathbb{P}^{3} \cong \mathrm{Bl}_{P} X \tag{2.1.2}
\end{equation*}
$$

i.e. the blow-up of $\mathbb{P}^{3}$ along the curve $C$ is isomorphic to the blow-up of $X$ at the singular point $P$.

Proof. As $X$ is a cubic hypersurface in $\mathbb{P}^{4}$, it is given as the zero set of a single homogeneous polynomial $f\left(x_{0}, x_{1}, x_{2}, x_{3}, x_{4}\right)$ of degree three. The coefficient of $x_{0}^{3}$ in $f$ must be zero, otherwise $X$ would not contain the point $P$. Similarly, the coefficients of the terms $x_{0}^{2} x_{i},(1 \leq i \leq 4)$ must be zero, otherwise $P$ would be a smooth point of $X$. Therefore the equation of $X$ can be written
in the form

$$
\begin{equation*}
x_{0} Q\left(x_{1}, x_{2}, x_{3}, x_{4}\right)+F\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0 \tag{2.1.3}
\end{equation*}
$$

where $Q$ is a homogeneous polynomial of degree two and $F$ is a homogeneous polynomial of degree three. Here $Q$ must be nonzero, because otherwise the singularity at $P$ would have multiplicity three. Similarly, $F$ is nonzero, since otherwise $X$ would be the union of a hyperplane and a quadric, and it would have nonisolated singularities. For the same reason $Q$ and $F$ cannot have common factors.

Next, we want to find the image $C$ of all lines lying in $X$ and passing through $P$ along the projection $\pi$. Let $\left(0: x_{1}: x_{2}: x_{3}: x_{4}\right)$ be an arbitrary point of the hyperplane $\left\{x_{0}=0\right\}$. Then the line $\mathbb{P}^{1}$ connecting $\left(0: x_{1}: x_{2}: x_{3}: x_{4}\right)$ and $P=(1: 0: 0: 0: 0)$ is given by ( $\left.\mu: \lambda x_{1}: \lambda x_{2}: \lambda x_{3}: \lambda x_{4}\right)$, where $(\mu: \lambda)$ are homogeneous parameters. Plugging this into equation (2.1.3) we get

$$
\begin{equation*}
\mu Q\left(\lambda x_{1}, \lambda x_{2}, \lambda x_{3}, \lambda x_{4}\right)+F\left(\lambda x_{1}, \lambda x_{2}, \lambda x_{3}, \lambda x_{4}\right)=0 \tag{2.1.4}
\end{equation*}
$$

then using that $\operatorname{deg} Q=2, \operatorname{deg} F=3$ :

$$
\begin{equation*}
\mu \lambda^{2} Q\left(x_{1}, x_{2}, x_{3}, x_{4}\right)+\lambda^{3} F\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0 \tag{2.1.5}
\end{equation*}
$$

When an entire line lies in $X$, then this equation must hold for any $(\mu: \lambda)$. The only way this can happen is when the coefficients of $\mu \lambda^{2}$ and $\lambda^{3}$ are zero. Thus the projection $C$ into $\mathbb{P}^{3}$ of the lines lying inside $X$ and containing the singular point $P$ is given by the equations

$$
\left\{\begin{array}{l}
Q\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0  \tag{2.1.6}\\
F\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0
\end{array}\right.
$$

Since $Q$ and $F$ have no common factors, $C$ has pure dimension one, and it is a complete intersection of type $(2,3)$.

Next, we want to find $\mathrm{Bl}_{C} \mathbb{P}^{3}$, the blow-up of $\mathbb{P}^{3}$ along the curve $C$. The result below (the equation of $\mathrm{Bl}_{C} \mathbb{P}^{3}$ ) also follows from standard results on blowing up regular sequences, see e.g. [EH00,

Exercise IV-26, p. 173]. Let's consider the open set $U_{1} \cong \mathbb{C}^{3} \subset \mathbb{P}^{3}$ given by $x_{1} \neq 0$. In $U_{1}$ the curve $C$ is given by the equations

$$
\left\{\begin{array}{l}
Q\left(1, x_{2}, x_{3}, x_{4}\right)=0  \tag{2.1.7}\\
F\left(1, x_{2}, x_{3}, x_{4}\right)=0
\end{array}\right.
$$

Then $\mathrm{Bl}_{C \cap U_{1}} U_{1} \subset \mathbb{C}^{3} \times \mathbb{P}^{1}$ is given by the equation

$$
\begin{equation*}
a_{0} Q\left(1, x_{2}, x_{3}, x_{4}\right)=a_{1} F\left(1, x_{2}, x_{3}, x_{4}\right) \tag{2.1.8}
\end{equation*}
$$

where $\left(a_{0}: a_{1}\right)$ are homogeneous coordinates of $\mathbb{P}^{1}$. We get similar equations for the open sets $U_{i}, 1 \leq i \leq 4$. The blow-up $\mathrm{Bl}_{C} \mathbb{P}^{3}$ is then a variety that we receive by gluing the blow-ups $\mathrm{Bl}_{C \cap U_{i}} U_{i}$ together. That we can do this simply follows from the fact that the blow-up of a manifold along a subvariety exists.

Next, we compute $\mathrm{Bl}_{P} X$, the blow-up of the variety $X$ at the singular point $P$ which will be a subvariety of $\mathbb{P}^{4} \times \mathbb{P}^{3}$. If the homogeneous coordinates of $\mathbb{P}^{3}$ are given by ( $\left.y_{1}: y_{2}: y_{3}: y_{4}\right)$, we consider the open set $\mathbb{P}^{4} \times \mathbb{C}^{3} \subset \mathbb{P}^{4} \times \mathbb{P}^{3}$ given by $y_{1} \neq 0$. Then we have the following equations for the blow-up in $\mathbb{P}^{4} \times \mathbb{C}^{3}$ :

$$
\begin{align*}
x_{0} Q\left(x_{1}, x_{2}, x_{3}, x_{4}\right) & +F\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0  \tag{2.1.9}\\
x_{2} & =x_{1} y_{2}  \tag{2.1.10}\\
x_{3} & =x_{1} y_{3}  \tag{2.1.11}\\
x_{4} & =x_{1} y_{4} . \tag{2.1.12}
\end{align*}
$$

After substitutions, the first equation becomes

$$
\begin{equation*}
x_{0} Q\left(x_{1}, x_{1} y_{2}, x_{1} y_{3}, x_{1} y_{4}\right)+F\left(x_{1}, x_{1} y_{2}, x_{1} y_{3}, x_{1} y_{4}\right)=0 \tag{2.1.13}
\end{equation*}
$$

Then pulling out $x_{1}$ gives:

$$
\begin{equation*}
x_{1}^{2}\left(x_{0} Q\left(1, y_{2}, y_{3}, y_{4}\right)+x_{1} F\left(1, y_{2}, y_{3}, y_{4}\right)\right)=0 \tag{2.1.14}
\end{equation*}
$$

Here the factor $x_{1}^{2}$ represents the exceptional set ( $x_{1}=0$ gives $x_{2}=x_{3}=x_{4}=0$ ), so we must disregard it. Thus the blow-up in $\mathbb{P}^{4} \times \mathbb{C}^{3}$ is given by:

$$
\begin{gather*}
x_{0} Q\left(1, y_{2}, y_{3}, y_{4}\right)+x_{1} F\left(1, y_{2}, y_{3}, y_{4}\right)=0  \tag{2.1.15}\\
x_{2}=x_{1} y_{2}, \quad x_{3}=x_{1} y_{3}, \quad x_{4}=x_{1} y_{4} \tag{2.1.16}
\end{gather*}
$$

We can in fact write this as a subvariety of $\mathbb{P}^{1} \times \mathbb{C}^{3}$ by simply taking the projection from $\mathbb{P}^{4} \times \mathbb{C}^{3}$ by forgetting the coordinates $x_{2}, x_{3}, x_{4}$ and the last three equations. Then the blow-up becomes a subvariety of $\mathbb{P}^{1} \times \mathbb{C}^{3}$ given by the single equation

$$
\begin{equation*}
x_{0} Q\left(1, y_{2}, y_{3}, y_{4}\right)+x_{1} F\left(1, y_{2}, y_{3}, y_{4}\right)=0 . \tag{2.1.17}
\end{equation*}
$$

We get similar equations for the other open patches inside the sets $\left\{y_{i} \neq 0\right\}$. Comparing equations (2.1.8) and (2.1.17) we see that the open patches of $\mathrm{Bl}_{C} \mathbb{P}^{3}$ and $\mathrm{Bl}_{P} X$ inside $\mathbb{P}^{1} \times \mathbb{C}^{3}$ are isomorphic. The transition functions between the different open patches must agree for the two blow-ups, because in both cases they are derived from the usual transition functions between the standard open affine subsets of the projective space $\mathbb{P}^{3}$. Thus $\mathrm{Bl}_{C} \mathbb{P}^{3}$ is isomorphic to $\mathrm{Bl}_{P} X$.

We now show the following well-known result (see e.g., the references in [CMJL12, §1.2, p. 6]). For completeness, we include a proof here.

Theorem 2.1.18 (e.g., [CML09, §3], [CMJL12, Prop. 1.3]). If $X$ has isolated singularities only, the singularities of the blow-up $\mathrm{Bl}_{P} X$ of $X$ at $P$ are in bijection with the singularities of the (2,3)-curve $C$, and along this bijection the corresponding singularities have the same singularity types.

Proof. By Theorem 2.1.1 we have $\mathrm{Bl}_{C} \mathbb{P}^{3} \cong \mathrm{Bl}_{P} X$, therefore it is enough to see that the singularities of $\mathrm{Bl}_{C} \mathbb{P}^{3}$ are in bijection with the singularities of $C$, and this bijection respects the singularity type. All singularities of $\mathrm{Bl}_{C} \mathbb{P}^{3}$ must be in the exceptional set, therefore it is enough to prove that each point above a non-singular point of $C$ is non-singular, while above any singular point $p$ of $C$ there is exactly one singular point in the blow-up with the same singularity type as $p$.

So let's fix a point $p=\left(y_{1}: y_{2}: y_{3}: y_{4}\right) \in C$ and let's examine the points of the blow-up above $p$. From the proof of Theorem 2.1.1 we know that $C$ is given by the equations

$$
\left\{\begin{array}{l}
Q\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0  \tag{2.1.19}\\
F\left(x_{1}, x_{2}, x_{3}, x_{4}\right)=0
\end{array}\right.
$$

where $Q$ and $F$ are nonzero homogeneous quadratic and cubic polynomials. By our assumptions it is not possible that both $Q$ and $F$ are singular at $p$, because then $X$ would be singular along the entire line connecting $P$ and the point $p \in \mathbb{P}^{3} \cong\left\{x_{0}=0\right\}$ and this would contradict the assumption that $X$ has isolated singularities only. To see this we take the derivative of the defining polynomial of $X$ (see equation (2.1.3)) to get

$$
\begin{gather*}
{\left[Q\left(x_{1}, \ldots, x_{4}\right) \quad x_{0} \frac{\partial}{\partial x_{1}} Q\left(x_{1}, \ldots, x_{4}\right)+\frac{\partial}{\partial x_{1}} F\left(x_{1}, \ldots, x_{4}\right) \quad \ldots\right.}  \tag{2.1.20}\\
\left.\ldots \quad x_{0} \frac{\partial}{\partial x_{4}} Q\left(x_{1}, \ldots, x_{4}\right)+\frac{\partial}{\partial x_{4}} F\left(x_{1}, \ldots, x_{4}\right)\right] .
\end{gather*}
$$

If we plug in the general point $\left(\mu: \lambda y_{1}: \lambda y_{2}: \lambda y_{3}: \lambda y_{4}\right)$ of the line connecting $P$ and $p$ we get

$$
\begin{gather*}
{\left[Q\left(\lambda y_{1}, \ldots, \lambda y_{4}\right) \quad \mu \partial_{1} Q\left(\lambda y_{1}, \ldots, \lambda y_{4}\right)+\partial_{1} F\left(\lambda y_{1}, \ldots, \lambda y_{4}\right)\right.}
\end{gather*} \quad \ldots .
$$

If $p$ is a singular point of both $Q$ and $F$, this Jacobian is zero for any $(\mu: \lambda)$, therefore at $p$ at least one of $Q$ and $F$ is non-singular.

Let's apply a local analytic transformation to a neighborhood of $p$ in $\mathbb{P}^{3}$ such that $p$ is taken to the origin of $\mathbb{C}^{3}$, while $z=0$ gives locally either the surface $Q$ or $F$ (we pick one that is non-singular at $p$ ). Then the other surface of $Q$ and $F$ will be given by some equation $h(x, y, z)=0$, with $h$ complex analytic. The curve $C$ is then given locally by the equations $z=0, h(x, y, 0)=0$ (thus $C$ becomes a planar curve) and the singularity type of $C$ at $p$ will be given by the function $h(x, y, 0)$. By another analytic transformation (in the $x, y$ coordinates only) we can write $h(x, y, 0)$ in the
standard polynomial form $q(x, y)$ according to the singularity type of $C$ at the point $p$. Then the blow-up of $\mathbb{C}^{3}$ along the curve given by $z=q(x, y)=0$ is given in $\mathbb{C}^{3} \times \mathbb{P}^{1}$ by the equation

$$
\begin{equation*}
a_{0} z-a_{1} q(x, y)=0 \tag{2.1.22}
\end{equation*}
$$

where $\left(a_{0}: a_{1}\right)$ are homogeneous coordinates of $\mathbb{P}^{1}$. The Jacobian of this is given by

$$
\left[\begin{array}{lllll}
-a_{1} \partial_{x} q(x, y) & -a_{1} \partial_{y} q(x, y) & a_{0} & z & -q(x, y) \tag{2.1.23}
\end{array}\right] .
$$

To get a singular point we must have $a_{0}=0$, therefore above the origin there can be at most one point $w$ where the blow-up is singular, and that is given by $\left(a_{0}: a_{1}\right)=(0: 1),(x, y, z)=(0,0,0)$. From the first two entries of the Jacobian we see that if $C$ is non-singular at $p$, the blow-up is nonsingular at $w$, therefore above a non-singular point of $C$ all points of the blow-up are non-singular. It is also clear that if $p$ is a singular point of $C$ (i.e. $q(x, y)$ is singular at $(0,0)$ ), then $w$ is also a singular point of the blow-up. To see that the two singularity types are the same, let's write equation (2.1.22) in the open set $\mathbb{C}^{3} \times \mathbb{C}$ given by $a_{1} \neq 0$. We can pick $a_{1}=1$ and write

$$
\begin{equation*}
q(x, y)-a_{0} z=0 \tag{2.1.24}
\end{equation*}
$$

as an equation in $\mathbb{C}^{4}$. Applying the linear transformation

$$
\begin{equation*}
a_{0}=u+i v, \quad z=-u+i v \tag{2.1.25}
\end{equation*}
$$

the equation transforms into

$$
\begin{equation*}
q(x, y)+u^{2}+v^{2}=0 \tag{2.1.26}
\end{equation*}
$$

Thus the type of the singularity is determined by $q(x, y)$ and therefore $C$ has the same singularity type at $p$ as the blow-up has at $w$.

### 2.2 Cohomology of a Blow-up

In this section we review some basic facts about the cohomology of a blow-up. This is standard (see e.g., [GH78, p. 605]). For completeness, we include detailed proofs here. Let $M$ be a complex manifold and $Y \subset M$ a submanifold. Let $\widetilde{M}$ denote $\mathrm{Bl}_{Y} M$, the blow-up of $M$ along $Y, \pi: \widetilde{M} \rightarrow M$ the map of the blow-up, and $E=\pi^{-1}(Y) \subset \widetilde{M}$ the exceptional set. For computing the cohomology of $\widetilde{M}$ we have the following

Theorem 2.2.1 ([GH78, p. 605]). For any $n \geq 0$ the cohomology of the blow-up is given by

$$
\begin{equation*}
H^{n}(\widetilde{M}, \mathbb{C})=\pi^{*}\left(H^{n}(M, \mathbb{C})\right) \oplus\left(H^{n}(E, \mathbb{C}) / \pi_{\mid E}^{*}\left(H^{n}(Y, \mathbb{C})\right)\right) \tag{2.2.2}
\end{equation*}
$$

and this formula respects the Hodge-decomposition, i.e. for any $p, q \geq 0$ we have

$$
\begin{equation*}
H^{p, q}(\widetilde{M})=\pi^{*}\left(H^{p, q}(M)\right) \oplus\left(H^{p, q}(E) / \pi_{\left.\right|_{E}}^{*}\left(H^{p, q}(Y)\right)\right) . \tag{2.2.3}
\end{equation*}
$$

Formula (2.2.2) is also true with the integer cohomologies $H^{n}(\cdot, \mathbb{Z}) /\{$ torsion cocycles $\}$.
Proof. We want to use Mayer-Vietoris sequences for $M$ and $\widetilde{M}$. We will decompose $M$ as the union of a tubular neighborhood of $Y$ and the open set $M-Y$, and similarly, we will write $\widetilde{M}$ as the union of a neighborhood of $E$ and the open set $\widetilde{M}-E$. The two decompositions will be compatible along $\pi$. First let's choose $U$ to be a tubular neighborhood of $Y$, and $\widetilde{U}=\pi^{-1}(U) \subset \widetilde{M}$ its preimage along $\pi$, which is a neighborhood of $E$. We also introduce the following open sets:

$$
\begin{align*}
M^{\circ} & =M-Y  \tag{2.2.4}\\
\widetilde{M}^{\circ} & =\widetilde{M}-E=\pi^{-1}\left(M^{\circ}\right)  \tag{2.2.5}\\
U^{\circ} & =U-Y  \tag{2.2.6}\\
\widetilde{U}^{\circ} & =\widetilde{U}-E=\pi^{-1}\left(U^{\circ}\right) . \tag{2.2.7}
\end{align*}
$$

With this notation we have

$$
\begin{equation*}
M=M^{\circ} \cup U, \quad U^{\circ}=M^{\circ} \cap U \tag{2.2.8}
\end{equation*}
$$

which gives the Mayer-Vietoris sequence

$$
\begin{equation*}
\cdots \rightarrow H^{n-1}\left(U^{\circ}, \mathbb{C}\right) \rightarrow H^{n}(M, \mathbb{C}) \rightarrow H^{n}\left(M^{\circ}, \mathbb{C}\right) \oplus H^{n}(U, \mathbb{C}) \rightarrow H^{n}\left(U^{\circ}, \mathbb{C}\right) \rightarrow \cdots \tag{2.2.9}
\end{equation*}
$$

and similarly

$$
\begin{equation*}
\widetilde{M}=\widetilde{M}^{\circ} \cup \widetilde{U}, \quad \widetilde{U}^{\circ}=\widetilde{M}^{\circ} \cap \widetilde{U} \tag{2.2.10}
\end{equation*}
$$

gives the sequence

$$
\begin{equation*}
\cdots \rightarrow H^{n-1}\left(\tilde{U}^{\circ}, \mathbb{C}\right) \rightarrow H^{n}(\widetilde{M}, \mathbb{C}) \rightarrow H^{n}\left(\widetilde{M}^{\circ}, \mathbb{C}\right) \oplus H^{n}(\widetilde{U}, \mathbb{C}) \rightarrow H^{n}\left(\widetilde{U}^{\circ}, \mathbb{C}\right) \rightarrow \cdots \tag{2.2.11}
\end{equation*}
$$

The map $\pi$ is an isomorphism outside of $E$ and $Y$, therefore we have the isomorphisms

$$
\begin{gather*}
\pi_{\left.\right|_{\mathbb{M}^{\circ}}}: \widetilde{M}^{\circ} \rightarrow M^{\circ}  \tag{2.2.12}\\
\pi_{\left.\right|_{\tilde{U}^{\circ}}}: \widetilde{U}^{\circ} \rightarrow U^{\circ} \tag{2.2.13}
\end{gather*}
$$

which in turn induce cohomology isomorphisms

$$
\begin{align*}
& \pi_{\left.\right|_{\widetilde{M}^{\circ}}}: H^{n}\left(M^{\circ}, \mathbb{C}\right) \rightarrow H^{n}\left(\widetilde{M}^{\circ}, \mathbb{C}\right)  \tag{2.2.14}\\
& \pi_{\left.\right|_{\tilde{U}^{\circ}} ^{*}}^{*}: H^{n}\left(U^{\circ}, \mathbb{C}\right) \rightarrow H^{n}\left(\widetilde{U}^{\circ}, \mathbb{C}\right) \tag{2.2.15}
\end{align*}
$$

Now $U$ being a tubular neighborhood of $Y$ means that there is a contraction

$$
\begin{align*}
& f: U \times[0,1] \rightarrow U  \tag{2.2.16}\\
& f(z, 0)=z, \forall z \in U  \tag{2.2.17}\\
& f(y, t)=y, \forall y \in Y, \forall t \in[0,1]  \tag{2.2.18}\\
& f(z, 1) \in Y, \forall z \in U, \tag{2.2.19}
\end{align*}
$$

and $Y$ is a deformation retract of $U$. This means that they are homotopy equivalent and the inclusion $i: Y \hookrightarrow U$ induces an isomorphism $i^{*}: H^{n}(U, \mathbb{C}) \rightarrow H^{n}(Y, \mathbb{C})$. Using the universial property of blow-up ([Har77, Prop. II.7.14., Cor. II.7.15.]) $f$ induces a contraction $\tilde{f}$ of $\widetilde{U}$ to $E$ and therefore the inclusion $\tilde{\imath}: E \hookrightarrow \widetilde{U}$ induces an isomorphism $\tilde{\imath}^{*}: H^{n}(\widetilde{U}, \mathbb{C}) \rightarrow H^{n}(E, \mathbb{C})$.

Using the above isomorphisms and the functorial property of the Mayer-Vietoris sequence, which we apply to $\pi$, we get the following commutative diagram:

The second row is the same as (2.2.11), the third row as (2.2.9) and the arrows between them come from the functorial property of the Mayer-Vietoris sequence. Copying the first and fourth rows we
get:

The map $\pi^{*}: H^{n}(M, \mathbb{C}) \rightarrow H^{n}(\widetilde{M}, \mathbb{C})$ is injective. To see this, we consider de-Rham cohomology and the fact that $\pi$ is birational, i.e. an isomorphism away from closed sets. If $\varphi$ is a $C^{\infty} n$-form on $M$ that represents a non-zero cocycle, then by the de Rham theorem there is a piecewise smooth $n$-chain $\sigma$, such that $\int_{\sigma} \varphi \neq 0$. We can choose $\sigma$ such that it is transversal to $Y$. Then if $\tilde{\sigma}$ is the proper transform of $\sigma$ (which is an $n$-chain in $\widetilde{M}$ ), we have $\int_{\tilde{\sigma}} \pi^{*} \varphi=\int_{\sigma} \varphi \neq 0$, because $\pi$ is an isomorphism away from $Y$ and $E$. This proves that $\pi^{*}$ is injective. By theorem 2.2.24 below $\pi_{\left.\right|_{E}}^{*}: H^{n}(Y, \mathbb{C}) \rightarrow H^{n}(E, \mathbb{C})$ is also injective. We also need to prove that the map $H^{n}(\widetilde{M}, \mathbb{C}) \rightarrow$ $H^{n}(E, \mathbb{C})$ is surjective. Again, to see this, we consider de Rham cohomology: if $\varphi$ is a $C^{\infty} n$-form on $E$, it can be extended into an $C^{\infty}{ }_{n}$-form on $\widetilde{M}$ using a tubular neighborhood of $E$.

Using the above we can transform diagram (2.2.21) into the following:

The columns are exact, the last two rows are the rows of diagram (2.2.21), therefore exact, and
we want to prove that $\delta$, which is induced from $\alpha^{\prime}$, is an isomorphism. To prove injectivity, let $x \in \operatorname{Coker} \beta$ with $\delta(x)=0$. There is a $y \in B^{\prime}$, such that $\beta^{\prime}(y)=x$. Since $\gamma^{\prime}\left(\alpha^{\prime}(y)\right)=0$, there exists $z \in C_{1} \oplus C_{2}$, such that $\gamma(z)=\alpha^{\prime}(y)$. Now $\lambda^{\prime}\left(\alpha^{\prime}(y)\right)=0$, therefore $\lambda^{\prime}(\gamma(z))=0$ and $\lambda(z)=0$. Thus there exists some $b \in B$, such that $z=\alpha(b)$. Next, we have $\alpha^{\prime}(y-\beta(b))=\alpha^{\prime}(y)-\alpha^{\prime}(\beta(b))=$ $\alpha^{\prime}(y)-\gamma(\alpha(b))=\alpha^{\prime}(y)-\gamma(z)=0$, which gives that there exists $u \in A$, such that $\mu^{\prime}(u)=y-\beta(b)$. But since $\mu^{\prime}(u)=\beta(\mu(u))$, we have $y=\beta(b)+\beta(\mu(u))$. This gives that $x=\beta^{\prime}(y)=0$ and injectivity is proven. To prove surjectivity we use the fact that $\mathrm{pr}_{2} \circ \alpha^{\prime}$ is surjective (this is the map $H^{n}(\widetilde{M}, \mathbb{C}) \rightarrow H^{n}(E, \mathbb{C})$ above $)$. Let $x \in \operatorname{Coker} \gamma$ be arbitrary element. Since $\gamma^{\prime}$ is surjective, there exists $(u, v) \in C_{1} \oplus C_{2}^{\prime}$ with $\gamma^{\prime}(u, v)=x$. Since $\operatorname{pr}_{2} \circ \alpha^{\prime}$ is surjective, there exists $b \in B^{\prime}$, such that $\alpha^{\prime}(b)=\left(u_{2}, v\right)$, for some $u_{2} \in C_{1}$. Then $\gamma^{\prime}\left(\alpha^{\prime}(b)\right)=\gamma^{\prime}\left(u_{2}, v\right)=\gamma^{\prime}(u, v)+\gamma^{\prime}\left(u_{2}-u, 0\right)=$ $\gamma^{\prime}(u, v)+\gamma^{\prime}\left(\gamma\left(u_{2}-u, 0\right)\right)=x$. Therefore $x=\delta\left(\beta^{\prime}(b)\right)$, and $\delta$ is surjective.

Returning to our original notation and to diagram (2.2.21), the above gives that

$$
\begin{equation*}
H^{n}(\widetilde{M}, \mathbb{C}) / \pi^{*}\left(H^{n}(M, \mathbb{C})\right) \cong H^{n}(E, \mathbb{C}) / \pi_{\left.\right|_{E}}^{*}\left(H^{n}(Y, \mathbb{C})\right) \tag{2.2.23}
\end{equation*}
$$

which proves the first part of the theorem, since these cohomologies are vector spaces and thus subspaces are direct summands.

To prove the theorem for the $H^{p, q}$ cohomology, we notice that the above proof works for that case as well. We can use the sheaf cohomology version of the Mayer-Vietoris theorem, since $H^{p, q}(M) \cong$ $H^{q}\left(M, \Omega^{p}\right)$. In the diagram (2.2.20) all vertical maps are pullbacks, therefore they respect the Hodge decomposition. The maps $\pi^{*}$ and $\pi_{I_{E}}^{*}$ in diagram (2.2.21) are injective on the $H^{p, q}$ direct summands, since they are pullbacks and respect the Hodge decomposition, and similarly the map $H^{n}(\widetilde{M}, \mathbb{C}) \rightarrow H^{n}(E, \mathbb{C})$ is surjective on the $H^{p, q}$ components.

Theorem 2.2.24 ([BT82, §20]). If $k$ is the codimension of $Y$ in $M$, we have

$$
\begin{equation*}
H^{n}(E, \mathbb{C}) \cong \bigoplus_{i=0}^{k-1} H^{n-2 i}(Y, \mathbb{C})=H^{n}(Y, \mathbb{C}) \oplus H^{n-2}(Y, \mathbb{C}) \oplus \cdots \oplus H^{n-2 k+2}(Y, \mathbb{C}) \tag{2.2.25}
\end{equation*}
$$

and

$$
\begin{equation*}
H^{p, q}(E) \cong \bigoplus_{i=0}^{k-1} H^{p-i, q-i}(Y)=H^{p, q}(Y) \oplus H^{p-1, q-1}(Y) \oplus \cdots \oplus H^{p-k+1, q-k+1}(Y) \tag{2.2.26}
\end{equation*}
$$

Proof. The exceptional set $E$ is the projectivization $\mathbb{P}\left(N_{Y / M}\right)$ of the normal bundle $N_{Y / M}$ of $Y$ in $M$. The fibers on $N_{Y / M}$ have dimension $k$, and the fibers of $E \rightarrow Y$ are projective spaces $\mathbb{P}^{k-1}$. From the theory of the cohomology of the projectivization of a vector bundle ([BT82, §20]) we know that additively

$$
\begin{equation*}
H^{*}(E, \mathbb{C})=H^{*}(Y, \mathbb{C}) \otimes H^{*}\left(\mathbb{P}^{k-1}, \mathbb{C}\right) \tag{2.2.27}
\end{equation*}
$$

We can rewrite this as

$$
\begin{equation*}
H^{n}(E, \mathbb{C})=\bigoplus_{r+s=n} H^{r}(Y, \mathbb{C}) \otimes H^{s}\left(\mathbb{P}^{k-1}, \mathbb{C}\right) \tag{2.2.28}
\end{equation*}
$$

for any $n \geq 0$. Since the cohomology of the projective space is

$$
H^{s}\left(\mathbb{P}^{k-1}, \mathbb{C}\right)= \begin{cases}\mathbb{C} & \text { if } \quad 2 \mid s, \quad 0 \leq s \leq 2 k-2  \tag{2.2.29}\\ 0 & \text { else },\end{cases}
$$

we obtain the first statement of the theorem. To prove (2.2.26), we note that the tensor product in (2.2.28) is realized as the wedge product of differential forms when we consider de Rham cohomology. In fact, let $\eta$ be a 2-form on $E$, such that the restriction to any fiber gives a cocycle $\left[\eta_{\mid \mathbb{P} k-1}\right]$ that generates $H^{2}\left(\mathbb{P}^{k-1}, \mathbb{C}\right)=\mathbb{C}$, i.e. it represents a hyperplane cocycle. Such $\eta$ exists by [BT82, p. 270]. Then (2.2.28) becomes

$$
\begin{equation*}
H^{n}(E, \mathbb{C})=\bigoplus_{i=0}^{k-1} H^{n-2 i}(Y, \mathbb{C}) \wedge\left[\eta^{i}\right] \tag{2.2.30}
\end{equation*}
$$

where $H^{r}(Y, \mathbb{C}) \subset H^{r}(E, \mathbb{C})$ through the inclusion $\pi_{\left.\right|_{E}}^{*}$. Since $\left[\eta^{i}\right] \in H^{i, i}(E)$, we obtain the second statement of the theorem.

### 2.3 Cubic Threefold with a Single $A_{1}$ or $A_{2}$ Singularity

In this section we describe the intermediate Jacobian of the desingularization of a cubic threefold with a single $A_{1}$ or $A_{2}$ singularity. We show in theorem 2.3.15 that it is the Jacobian of the (2,3)curve described above. These results are due to Clemens and Griffiths [CG72], and we include the proof here for completeness. Let $X \subset \mathbb{P}^{4}$ be a cubic threefold with a single $A_{1}$ or $A_{2}$ singularity at $P \in X$. By theorem 2.1.1 $\mathrm{Bl}_{P} X=\mathrm{Bl}_{C} \mathbb{P}^{3}$, where $C$ is the (2,3)-curve introduced earlier, and by theorem 2.1.18 the singularities of $C$ are the same as that of $\mathrm{Bl}_{P} X$. Blowing up $X$ at $P$ will desingularize $X$ at $P$, since it is either an $A_{1}$ or an $A_{2}$ point, therefore both $\mathrm{Bl}_{P} X$ and the curve $C$ are non-singular. Our goal is to find the intermediate Jacobian of the desingularization $\widetilde{X}=\mathrm{Bl}_{P} X=\mathrm{Bl}_{C} \mathbb{P}^{3}$. For this we find the cohomology and the Hodge diamond of $\widetilde{X}$. Let $\pi: \widetilde{X} \rightarrow \mathbb{P}^{3}$ be the map of the blow-up along $C$, and let $E=\pi^{-1}(C)$ be the exceptional divisor. Then $\operatorname{dim} E=2$ and the fibers of $\pi_{\left.\right|_{E}}$ are $\mathbb{P}^{1}$. By theorem 2.2.24 we have

$$
\begin{align*}
H^{n}(E, \mathbb{C}) & \cong H^{n}(C, \mathbb{C}) \oplus H^{n-2}(C, \mathbb{C})  \tag{2.3.1}\\
H^{p, q}(E) & \cong H^{p, q}(C) \oplus H^{p-1, q-1}(C) . \tag{2.3.2}
\end{align*}
$$

More precisely, formula (2.2.30) gives

$$
\begin{equation*}
H^{n}(E, \mathbb{C})=H^{n}(C, \mathbb{C}) \oplus H^{n-2}(C, \mathbb{C}) \wedge[\eta], \tag{2.3.3}
\end{equation*}
$$

where $\eta$ is a $(1,1)$-form on $E$, such that its restrictions on the fibers generate $H^{2}\left(\mathbb{P}^{1}, \mathbb{C}\right)$. We then have the following cohomologies:

$$
\begin{align*}
& H^{4}(E, \mathbb{C})=\mathbb{C}  \tag{2.3.4}\\
& H^{3}(E, \mathbb{C})=H^{1}(C, \mathbb{C}) \wedge[\eta]  \tag{2.3.5}\\
& H^{2}(E, \mathbb{C})=H^{2}(C, \mathbb{C}) \oplus H^{0}(C, \mathbb{C}) \wedge[\eta] \cong \mathbb{C} \oplus \mathbb{C}  \tag{2.3.6}\\
& H^{1}(E, \mathbb{C})=H^{1}(C, \mathbb{C})  \tag{2.3.7}\\
& H^{0}(E, \mathbb{C})=\mathbb{C} \tag{2.3.8}
\end{align*}
$$

The Hodge diamond of $E$ :

$$
\begin{equation*}
 \tag{2.3.9}
\end{equation*}
$$

Next we want to use theorem 2.2.1, so we compute

$$
\begin{align*}
& H^{2}(E, \mathbb{C}) / \pi_{\left.\right|_{E}}^{*}\left(H^{2}(C, \mathbb{C})\right)=H^{0}(C, \mathbb{C}) \wedge[\eta] \cong \mathbb{C}  \tag{2.3.10}\\
& H^{1}(E, \mathbb{C}) / \pi_{\left.\right|_{E}}^{*}\left(H^{1}(C, \mathbb{C})\right)=0  \tag{2.3.11}\\
& H^{0}(E, \mathbb{C}) / \pi_{\left.\right|_{E}}^{*}\left(H^{0}(C, \mathbb{C})\right)=0 . \tag{2.3.12}
\end{align*}
$$

After "factoring out" the Hodge diamond of $C$ from that of $E$ we get:

To get the Hodge diamond of $\tilde{X}$, we have to add the Hodge diamond of $\mathbb{P}^{3}$ to the above, which gives:

This means that $H^{1,2}(\widetilde{X}) \oplus H^{0,3}(\widetilde{X}) \cong H^{0,1}(C)$, and $H^{3}(\widetilde{X}, \mathbb{C}) \cong H^{1}(C, \mathbb{C})$. This proves the following

Theorem 2.3.15 ([CG72]). The intermediate Jacobian of the desingularization $\widetilde{X}=\mathrm{Bl}_{P} X$ of a cubic threefold with a single $A_{1}$ or $A_{2}$ singularity is isomorphic to the Jacobian $J C$ of the (2,3)-curve
$C$.

### 2.4 Cubic Threefold with a Single $A_{3}$ Singularity

Let $X \subset \mathbb{P}^{4}$ be a cubic threefold with a single $A_{3}$ singularity at $P \in X$. Blowing up $X$ once at $P$ results in a singular threefold with a node, so we have to blow it up a second time to get the desingularization $\widetilde{X}$ of $X$. Since the singularities of $\mathrm{Bl}_{P} X \cong \mathrm{Bl}_{C} \mathbb{P}^{3}$ are the same as the singularities of $C$, the curve $C$ is singular with a node. Thus we do not want to consider the Jacobian of $C$, but rather the Jacobian of the normalization of $C$, i.e. the blow-up of $C$ at the node. To find the intermediate Jacobian of $\tilde{X}$, we want to see how it relates to the Jacobian of the normalization of $C$. For this we want to find some relationship between $\widetilde{X}$ and $\mathrm{Bl}_{N C} \mathrm{Bl}_{Q} \mathbb{P}^{3}$, where $Q$ is the node of $C$ and $N C=\mathrm{Bl}_{Q} C$ is the normalization of $C$. In other words to get $Y=\mathrm{Bl}_{N C} \mathrm{Bl}_{Q} \mathbb{P}^{3}$ we first blow up $\mathbb{P}^{3}$ at the node of $C$, then blow up the result along the proper transform of $C$. Notice that an alternative way to get $\widetilde{X}$ is first blowing up $\mathbb{P}^{3}$ along $C$, then blowing up the result at the node (which is a point above $Q$, the node of $C$ ), thus to get $Y$ we essentially switch the order of these two blow-ups.

First we consider the picture locally around $Q$. Since $Q$ is a node of $C$, there exists some neighborhood $U$ of $Q$ and an analytic isomorphism $\xi: U \rightarrow \mathbb{C}^{3}$, that gives an analytic isomorphism between $C \cap U$ and $D=\left\{(x, y, z) \in \mathbb{C}^{3} \mid x y=z=0\right\}$, i.e. the union of the $x$ and $y$ axes. We need to compare two series of blow-ups: one, the blow-up of $\mathbb{C}^{3}$ along $D$ followed by the blow-up of the result at the node of the result (there has to be one node above the origin); two, the blow-up of $\mathbb{C}^{3}$ at the origin followed by the blow-up of the result along the proper transform of $D$. We hope to find further blow-ups of these spaces that will result in the same threefold. To do this we use the theory of toric varieties. We follow the treatment of the theory as in [CLS11], and we rely on results of Chapters 1-3, 7, 11.

Let $N=\mathbb{N}^{3}, N_{\mathbb{R}}=N \otimes \mathbb{R}=\mathbb{R}^{3}$ and $\left(e_{1}, e_{2}, e_{3}\right)$ the standard basis of $N_{\mathbb{R}}$. Let $\sigma=$ Cone $\left(e_{1}, e_{2}, e_{3}\right) \subset N_{\mathbb{R}}$ be the cone of the first octant, which is strongly convex and rational. The following picture depicts the intersection of $\sigma$ with the plane lying on the endpoints of the vectors $e_{1}, e_{2}, e_{3}$.

Below we use the same plane to get two dimensional representations of cones and fans. The affine toric variety of $\sigma$ is $U_{\sigma}=\mathbb{C}^{3}$. We note the closures of the orbits of the faces of $\sigma$ :

$$
\begin{align*}
& V\left(\operatorname{Cone}\left(e_{1}\right)\right)=\text { the } y z \text {-plane }  \tag{2.4.1}\\
& V\left(\operatorname{Cone}\left(e_{2}\right)\right)=\text { the } x z \text {-plane }  \tag{2.4.2}\\
& V\left(\operatorname{Cone}\left(e_{3}\right)\right)=\text { the } x y \text {-plane }  \tag{2.4.3}\\
& V\left(\operatorname{Cone}\left(e_{1}, e_{2}\right)\right)=\text { the } z \text {-axis }  \tag{2.4.4}\\
& V\left(\operatorname{Cone}\left(e_{1}, e_{3}\right)\right)=\text { the } y \text {-axis }  \tag{2.4.5}\\
& V\left(\operatorname{Cone}\left(e_{2}, e_{3}\right)\right)=\text { the } x \text {-axis } \tag{2.4.6}
\end{align*}
$$

To construct $\mathrm{Bl}_{D} \mathbb{C}^{3}$, let $\Sigma_{1}$ be the fan containing the cones $\sigma_{a}=\operatorname{Cone}\left(e_{1}, e_{2}, e_{2}+e_{3}, e_{1}+e_{3}\right)$ and $\sigma_{b}=\operatorname{Cone}\left(e_{1}+e_{3}, e_{2}+e_{3}, e_{3}\right)$ and all of their faces. Thus we get $\Sigma_{1}$ if we subdivide $\sigma$ along the new face Cone $\left(e_{1}+e_{3}, e_{2}+e_{3}\right)$.

Proposition 2.4.7. The toric variety $T_{\Sigma_{1}}$ is the blow-up of $\mathbb{C}^{3}$ along the union of the $x$ and $y$ axes, i.e. $T_{\Sigma_{1}} \cong \mathrm{Bl}_{D} \mathbb{C}^{3}$.

Proof. We need to construct $U_{\sigma_{a}}$ and $U_{\sigma_{b}}$ and see how they glue together. To get the dual cones we need to find the facet normals of $\sigma_{a}$ and $\sigma_{b}$. A facet normal can be found by taking the cross
product in $\mathbb{R}^{3}$ of the two generating vectors of the facet, e.g. $e_{1} \times e_{2}=e_{3}$ gives the normal to the facet that is represented by the bottom edge of the triangle in the diagram of $\Sigma_{1}$. This computation gives:

$$
\begin{gather*}
\sigma_{a}^{\vee}=\operatorname{Cone}\left(e_{3}, e_{1}, e_{1}+e_{2}-e_{3}, e_{2}\right) \subset M_{\mathbb{R}}  \tag{2.4.8}\\
\sigma_{b}^{\vee}=\operatorname{Cone}\left(e_{3}-e_{2}-e_{1}, e_{1}, e_{2}\right) \subset M_{\mathbb{R}}, \tag{2.4.9}
\end{gather*}
$$

where $M=N^{\vee}$ and $M_{\mathbb{R}}=M \otimes \mathbb{R}=N_{\mathbb{R}}^{\vee}$. We have to find generators of the semigroups $\sigma_{a}^{\vee} \cap M$ and $\sigma_{b}^{\vee} \cap M$. In fact in both cases the generators of the cones in $M_{\mathbb{R}}$ are also generators of the semigroups in $M$. To see this let

$$
\begin{equation*}
x=t_{1} e_{3}+t_{2} e_{1}+t_{3}\left(e_{1}+e_{2}-e_{3}\right)+t_{4} e_{2} \in \sigma_{a}^{\vee} \cap M, \quad t_{i} \in \mathbb{R}_{\geq 0} \tag{2.4.10}
\end{equation*}
$$

This gives

$$
\begin{equation*}
x=\left(t_{2}+t_{3}\right) e_{1}+\left(t_{4}+t_{3}\right) e_{2}+\left(t_{1}-t_{3}\right) e_{3} \tag{2.4.11}
\end{equation*}
$$

where the coefficients must be integers. If $t_{1} \geq t_{3}$, we are done. Otherwise we write

$$
\begin{equation*}
x=\left(t_{1}+t_{2}\right) e_{1}+\left(t_{1}+t_{4}\right) e_{2}+\left(t_{3}-t_{1}\right)\left(e_{1}+e_{2}-e_{3}\right) \tag{2.4.12}
\end{equation*}
$$

Since now $t_{3}-t_{1}$ is non-negative and integer, $t_{1}+t_{2}$ and $t_{1}+t_{4}$ are also integers, this proves that $\left\{e_{1}, e_{2}, e_{3}, e_{1}+e_{2}-e_{3}\right\}$ are generators of the semigroup $\sigma_{a}^{\vee} \cap M$. Similarly let

$$
\begin{equation*}
x=t_{1}\left(e_{3}-e_{2}-e_{1}\right)+t_{2} e_{1}+t_{3} e_{2} \in \sigma_{b}^{\vee} \cap M, \quad t_{i} \in \mathbb{R}_{\geq 0} \tag{2.4.13}
\end{equation*}
$$

We can rewrite this as

$$
\begin{equation*}
x=\left(t_{2}-t_{1}\right) e_{1}+\left(t_{3}-t_{1}\right) e_{2}+t_{1} e_{3} \tag{2.4.14}
\end{equation*}
$$

where the coefficients are integers, but this is only possible if the original coefficients in (2.4.13) are integers, which proves that $\left\{e_{3}-e_{2}-e_{1}, e_{1}, e_{2}\right\}$ are generators of $\sigma_{b}^{\vee} \cap M$.

The affine toric variety $U_{\sigma_{a}}$ is then defined as the Zariski closure of the image of $\left(\mathbb{C}^{*}\right)^{3} \ni$

$$
\begin{align*}
& \left(q_{1}, q_{2}, q_{3}\right) \mapsto\left(q_{3}, q_{1}, q_{1} q_{2} q_{3}^{-1}, q_{2}\right) \in \mathbb{C}^{4} . \text { Thus } \\
& U_{\sigma_{a}}=\mathbf{V}\left(\left\langle u_{1} u_{3}-u_{2} u_{4}\right\rangle\right), \quad\left\langle u_{1} u_{3}-u_{2} u_{4}\right\rangle \triangleleft \mathbb{C}\left[u_{1}, u_{2}, u_{3}, u_{4}\right] . \tag{2.4.15}
\end{align*}
$$

Similarly $U_{\sigma_{b}}$ is the Zariski closure of the image of $\left(\mathbb{C}^{*}\right)^{3} \ni\left(q_{1}, q_{2}, q_{3}\right) \mapsto\left(q_{3} q_{1}^{-1} q_{2}^{-1}, q_{1}, q_{2}\right) \in \mathbb{C}^{3}$. Thus $U_{\sigma_{b}} \cong \mathbb{C}^{3}$, and the coordinate ring is $\mathbb{C}\left[U_{\sigma_{b}}\right]=\mathbb{C}\left[v_{1}, v_{2}, v_{3}\right]$ (this also follows from the fact that $\sigma_{b}$ is generated by a $\mathbb{Z}$-basis of $\left.N\right)$. We can glue $U_{\sigma_{a}} \backslash \mathbf{V}\left(\left\langle u_{3}\right\rangle\right)$ and $U_{\sigma_{b}} \backslash \mathbf{V}\left(\left\langle v_{1}\right\rangle\right)$ with the isomorphism given by

$$
\begin{equation*}
u_{1}=v_{1} v_{2} v_{3}, \quad u_{2}=v_{2}, \quad u_{3}=\frac{1}{v_{1}}, \quad u_{4}=v_{3} . \tag{2.4.16}
\end{equation*}
$$

Since the union $D$ of the $x$ and $y$ axes is given by the ideal $\mathfrak{a}=\langle x y, z\rangle \triangleleft \mathbb{C}[x, y, z]$, the blow-up of $\mathbb{C}^{3}$ along $D$ is given in $\mathbb{P}^{1} \times \mathbb{C}^{3}$ by the equation $a_{0} x y=a_{1} z$, where $\left(a_{0}: a_{1}\right) \in \mathbb{P}^{1}$. We get an open affine cover by the sets $\left\{x y=a_{1} z\right\} \subset \mathbb{C}^{4}$ and $\left\{a_{0} x y=z\right\} \subset \mathbb{C}^{4}$ by setting $a_{0}=1$ first, then $a_{1}=1$. The identifications

$$
\begin{equation*}
a_{0}=v_{1}, \quad a_{1}=u_{3}, \quad x=u_{2}=v_{2}, \quad y=u_{4}=v_{3}, \quad z=u_{1} \tag{2.4.17}
\end{equation*}
$$

then show that the toric variety $T_{\Sigma_{1}}$ is indeed the blow-up $\mathrm{Bl}_{D} \mathbb{C}^{3}$.
For an alternative proof, we can construct the lattice polyhedron $P$ belonging to $\mathfrak{a}$ (as in [CLS11, §11.3]). The ideal $\mathfrak{a}$ is radical because it is generated by square-free monomials, therefore it is integrally closed (see [CLS11, Example 11.3.7.]). The polyhedron belonging to $\mathfrak{a}$ is then $P=\operatorname{Conv}\left(e_{1}+e_{2}, e_{3}\right)+\sigma^{\vee}$, where $\operatorname{Conv}\left(e_{1}+e_{2}, e_{3}\right)$ is the line segment between the two points. Since the facets of the recession cone of $P$ are coordinate planes, $P$ is normal and therefore $X_{P}=\mathrm{Bl}_{\mathfrak{a}} \mathbb{C}^{3}$. To find the fan in $N_{\mathbb{R}}$ that gives $X_{P}$ we note that $P$ has two vertices, $e_{1}+e_{2}$ and $e_{3}$. The facets joining $e_{1}+e_{2}$ have normal vectors that are the generators of $\sigma_{b}$ and the facets joining $e_{3}$ have normal vectors that are the generators of $\sigma_{a}$. This means that the fan corresponding to $P$ is $\Sigma_{1}$ and therefore $X_{\Sigma_{1}}=X_{P}=\mathrm{Bl}_{D} \mathbb{C}^{3}$.

The blow-up $\mathrm{Bl}_{D} \mathbb{C}^{3}$ has a node, and in the next step we want to find the blow-up of $\mathrm{Bl}_{D} \mathbb{C}^{3}$ at
the node. From Examples 11.1.12 and 11.2.12 of [CLS11] we know that this blow-up is given by the star subdivision $\Sigma_{2}=\Sigma_{1}^{*}(\tau)$ of $\Sigma_{1}$, where

$$
\begin{equation*}
\tau=\operatorname{Cone}\left(e_{1}+e_{2}+e_{3}\right)=\operatorname{Cone}\left(e_{1}, e_{2}+e_{3}\right) \cap \operatorname{Cone}\left(e_{2}, e_{1}+e_{3}\right) \tag{2.4.18}
\end{equation*}
$$

is the center line of $\sigma_{a}$. The toric variety $X_{\Sigma_{2}}$ is the one that we get by first blowing up $\mathbb{C}^{3}$ along the union of the $x$ and $y$ axes, then blowing up the singular point.

In the second series of blow-ups we first blow up $\mathbb{C}^{3}$ at the origin, then blow up the result along the proper transform of the union of the $x$ and $y$ axes. Again, we start from the cone $\sigma \subset N_{\mathbb{R}}$ which corresponds to $\mathbb{C}^{3}$. The origin is the orbit belonging to $\sigma$, i.e. $V(\sigma)=\{0\}$. If we let $\Sigma$ denote the fan whose only maximal cone is $\sigma$, as $\sigma$ is smooth the blow-up $\mathrm{Bl}_{0} \mathbb{C}^{3}$ is given by the star subdivision $\Sigma_{3}=\Sigma^{*}(\tau)$, where $\tau=\operatorname{Cone}\left(e_{1}+e_{2}+e_{3}\right)$, as defined earlier.

In $\Sigma_{3}$ we have the following orbit closures:

$$
\begin{gather*}
V\left(\operatorname{Cone}\left(e_{1}, e_{3}\right)\right)=\text { proper transform of the } y \text { axis }  \tag{2.4.19}\\
V\left(\operatorname{Cone}\left(e_{2}, e_{3}\right)\right)=\text { proper transform of the } x \text { axis }  \tag{2.4.20}\\
V\left(\operatorname{Cone}\left(e_{3}\right)\right)=\text { proper transform of the } x y \text { plane }  \tag{2.4.21}\\
V(\tau)=\text { the exceptional set }  \tag{2.4.22}\\
V\left(\operatorname{Cone}\left(\tau, e_{3}\right)\right)=V\left(\operatorname{Cone}\left(e_{3}\right)\right) \cap V(\tau) \tag{2.4.23}
\end{gather*}
$$

The orbit closure $V\left(\operatorname{Cone}\left(e_{3}\right)\right)$ can also be described as the $x y$ plane blown up at the origin and $V\left(\operatorname{Cone}\left(\tau, e_{3}\right)\right)$ as the exceptional set of the blow-up of the $x y$ plane at the origin.

In $\mathrm{Bl}_{0} \mathbb{C}^{3}$ the proper transforms of the $x$ and $y$ axes are disjoint, therefore blowing up $\mathrm{Bl}_{0} \mathbb{C}^{3}$ along the proper transform of the union of the two axes is the same as blowing it up twice consecutively along the proper transform of one axis then the other. To get the two consecutive blow-ups we take two consecutive star subdivisions of $\Sigma_{3}$. This gives $\Sigma_{4}=\left(\Sigma_{3}^{*}\left(\tau_{1}\right)\right)^{*}\left(\tau_{2}\right)$, where $\tau_{1}=\operatorname{Cone}\left(e_{1}+e_{3}\right)$ and $\tau_{2}=\operatorname{Cone}\left(e_{2}+e_{3}\right)$. This gives the blow-up that we want, because all cones of $\Sigma_{3}$ and $\Sigma_{3}^{*}\left(\tau_{1}\right)$ are smooth. Thus $X_{\Sigma_{4}}$ is the blow-up of $\mathbb{C}^{3}$ at the origin followed by the blow-up of the proper transform of the union of the $x$ and $y$ axes.

In the next step we construct a common refinement of the fans $\Sigma_{2}$ and $\Sigma_{4}$. It is given by adding the new ray

$$
\begin{equation*}
\tau_{3}=\operatorname{Cone}\left(e_{1}+e_{2}+2 e_{3}\right)=\operatorname{Cone}\left(\tau_{1}, \tau_{2}\right) \cap \operatorname{Cone}\left(\tau, e_{3}\right), \tag{2.4.24}
\end{equation*}
$$

and taking the star subdivision

$$
\begin{equation*}
\Sigma_{5}=\Sigma_{2}^{*}\left(\tau_{3}\right)=\Sigma_{4}^{*}\left(\tau_{3}\right) \tag{2.4.25}
\end{equation*}
$$

Since $\Sigma_{2}$ and $\Sigma_{4}$ are smooth, these refinements represent blow-ups. We obtain $\Sigma_{5}$ from $\Sigma_{2}$ by adding $\tau_{3}$ to Cone $\left(\tau_{1}, \tau_{2}\right)$ and subdividing, therefore $X_{\Sigma_{5}} \rightarrow X_{\Sigma_{2}}$ is the blow-up $\mathrm{Bl}_{V\left(\operatorname{Cone}\left(\tau_{1}, \tau_{2}\right)\right)} X_{\Sigma_{2}}$. By [CLS11, Prop. 11.1.10] the orbit closure $V\left(\operatorname{Cone}\left(\tau_{1}, \tau_{2}\right)\right)$ in $\Sigma_{1}$ is the total transform (the preimage) of $0 \in \mathbb{C}^{3}$ in $\mathrm{Bl}_{D} \mathbb{C}^{3}$, which is some curve $F$ isomorphic to $\mathbb{P}^{1}$. The orbit closure $V\left(\operatorname{Cone}\left(\tau_{1}, \tau_{2}\right)\right)$ in $\Sigma_{2}$ is then the proper transform of $F$ along the blow-up $X_{\Sigma_{2}} \rightarrow X_{\Sigma_{1}}$. This latter blow-up was at a node of $X_{\Sigma_{1}}$ which is actually on $F$. The proper transform of $F$ is still isomorphic to $\mathbb{P}^{1}$, therefore we get $X_{\Sigma_{5}}$ from $X_{\Sigma_{2}}$ by blowing it up along some curve isomorphic to $\mathbb{P}^{1}$. Similarly, we obtain $\Sigma_{5}$ from $\Sigma_{4}$ by adding $\tau_{3}$ to Cone $\left(\tau, e_{3}\right)$ and subdividing, therefore $X_{\Sigma_{5}} \rightarrow X_{\Sigma_{4}}$ is the blow-up $\operatorname{Bl}_{V\left(\operatorname{Cone}\left(\tau, e_{3}\right)\right)} X_{\Sigma_{4}}$. The orbit closure $V\left(\operatorname{Cone}\left(\tau, e_{3}\right)\right)$ in $\Sigma_{3}$ is the exceptional set of the blow-up of the $x y$ plane at the origin, therefore it is isomorphic to $\mathbb{P}^{1}$. Its proper transform in $X_{\Sigma_{4}}$ must also be isomorphic to $\mathbb{P}^{1}$, therefore we get $X_{\Sigma_{5}}$ from $X_{\Sigma_{4}}$ by blowing it up along some curve isomorphic to $\mathbb{P}^{1}$.

Getting back to the global picture, let's consider the following two series of blow-ups, both
starting from $\mathbb{P}^{3}$ :

where $R$ is the node of $\mathrm{Bl}_{C} \mathbb{P}^{3}, \eta$ is the proper transform along $\pi_{2}$ of the preimage along $\pi_{1}$ of $Q \in C, \widetilde{C}=N C=\mathrm{Bl}_{Q} C$ is the proper transform of $C$ along $\rho_{1}$ and $\nu$ is the proper transform along $\rho_{2}$ of the curve that consists of all the directions from $Q$ that are in the tangent plane of $C$ at $Q$ (since $C$ has a node at $Q$, it has a tangent plane and the directions in that tangent plane at $Q$ give a curve in the exceptional set of $\mathrm{Bl}_{Q} \mathbb{P}^{3}$ ). The curves $\eta$ and $\nu$ are isomorphic to $\mathbb{P}^{1}$.

There is an isomorphism between $X^{\#} \backslash \pi^{-1}(C)$ and $Z^{\#} \backslash \rho^{-1}(C)$, since both are isomorphic to $\mathbb{P}^{3} \backslash C$. These are isomorphisms between open dense sets. In fact more is true:

$$
\begin{equation*}
X^{\#} \backslash \pi^{-1}(Q) \cong Z^{\#} \backslash \rho^{-1}(Q) \cong \mathrm{Bl}_{C \backslash\{Q\}}\left(\mathbb{P}^{3} \backslash\{Q\}\right), \tag{2.4.27}
\end{equation*}
$$

since the blow-ups of (2.4.26) only differ at $Q$ and its preimages. To see that this isomorphism extends to an isomorphism $X^{\#} \cong Z^{\#}$ we use our result about toric varieties. This gives that

$$
\begin{equation*}
\pi^{-1}(U) \cong X_{\Sigma_{5}} \cong \rho^{-1}(U) \tag{2.4.28}
\end{equation*}
$$

where $U \subset \mathbb{P}^{3}$ was defined above as some small open neighborhood of $Q$. The isomorphism $\pi^{-1}(U) \cong \rho^{-1}(U)$ is compatible with $X^{\#} \backslash \pi^{-1}(Q) \cong Z^{\#} \backslash \rho^{-1}(Q)$, therefore $X^{\#} \cong Z^{\#}$. This proves the following

Theorem 2.4.29. Let $X \subset \mathbb{P}^{4}$ be a cubic threefold with a single $A_{3}$ singularity, and let $\widetilde{X}$ be its
desingularization which we get by blowing up the singular point twice. Then $\widetilde{X}$ can be obtained from a series of blow-ups and blow-downs as follows: blow up $\mathbb{P}^{3}$ at the node of the $(2,3)$-curve $C$, blow up the result along the normalization of $C$, blow up the result along the curve $\nu \cong \mathbb{P}^{1}$ and finally blow down the result along the curve $\eta \cong \mathbb{P}^{1}$.

Corollary 2.4.30. The intermediate Jacobian of the desingularization of $X$ is the Jacobian of the normalization of the $(2,3)$-curve $C$, i.e.

$$
\begin{equation*}
I J(\widetilde{X}) \cong J(N C) \tag{2.4.31}
\end{equation*}
$$

Proof. Using the theorems of $\S 2.2$ and the process in $\S 2.3$ we see that blowing up at a point or along a curve isomorphic to $\mathbb{P}^{1}$ does not change the third cohomology. On the other hand blowing up along $N C$ adds $H^{1}(N C, \mathbb{C})$ to $H^{3}(\cdot, \mathbb{C})$ and adds $H^{0,1}(N C)$ to $H^{1,2}(\cdot)$.

## Chapter 3

## Degenerations of Intermediate Jacobians of Cubic Threefolds

### 3.1 Cubic Surfaces

In this section $X$ is a surface in $\mathbb{P}^{3}$ given by a single homogeneous degree three polynomial. It will frequently be the case that we will want to cut a cubic threefold with a hyperplane in $\mathbb{P}^{4}$. The result will be a cubic surface, and we will be interested in lines on these possibly singular cubic surfaces. We give a short summary of the description of lines on cubic surfaces with some basic isolated singularities. The source of all these classical results is Cayley's famous Memoir on Cubic Surfaces ([Cy869]). In this section we use Cayley's original notation.

### 3.1.1 Non-singular cubic surfaces

If $X$ has no singularities, it contains exactly 27 lines, each with multiplicity one. There are 45 planes in $\mathbb{P}^{3}$ that intersect $X$ in a union of lines. The intersection in all 45 cases is a union of three distinct lines. Each of the 27 lines appears in 5 different planes as part of the intersection. The incidence relations between the lines and the planes are the following. There are six disjoint lines labelled from 1 to 6 . Another set of six disjoint lines are labelled from $1^{\prime}$ to $6^{\prime}$. Line $i$ intersects line $j^{\prime}$ if and only if $i \neq j$. There are 15 lines labelled $i j$ with $1 \leq i<j \leq 6$, i.e. lines $12,13, \ldots, 16,23, \ldots, 56$. Line $i j$ intersects line $k$ if and only if $k=i$ or $k=j$ and similarly line $i j$ intersects line $l^{\prime}$ if and only if $l=i$ or $l=j$. Finally, line $i j$ intersects line $k l$ if and only if $i, j, k, l$ are distinct indexes. The lines $i$ and $j^{\prime}$ determine the plane $i j^{\prime}$, where the third line of intersection is $i j$ if $i<j$ and $j i$
otherwise. There are $6 \times 5=30$ such planes. The lines $i j, k l, m n$ also determine a plane if all these indexes are distinct, that gives the remaining 15 planes.

### 3.1.2 $A_{1}$ cubic surfaces

In this case there are six lines labelled from 1 to 6 that go through the singular point and lie on a quadric cone which is the tangent cone to $X$ at the node. These lines have multiplicity two. There are 15 lines with multiplicity one, not containing the node. These are labelled $i j$, with $1 \leq i<j \leq 6$. For $i<j$ the lines $i, j$ and $i j$ make up the plane $i j$. These planes have multiplicity two. The lines $i j, k l, m n$ lie in a plane if and only if these indexes are distinct. These 15 planes have multiplicity one.

### 3.1.3 $\quad A_{2}$ cubic surfaces

Now the tangent cone at the singular point is a union of two planes which are labelled 123 and 456. Each of these planes has multiplicity six. In plane 123 the three lines labelled 1, 2 and 3 intersect at the singular point, and similarly in plane 456 the lines 4,5 and 6 intersect there. Thus the lines going through the singular point are 1 through 6 , and each of these lines has multiplicity three. The remaining lines have multiplicity one and they are labelled $i j$, with $i \in\{1,2,3\}, j \in\{4,5,6\}$. The planes $i j$ with $i \in\{1,2,3\}, j \in\{4,5,6\}$ contain the lines $i, j$ and $i j$, each having multiplicity three. There are six more planes, each with multiplicity one, made up of the lines $i j, k l, m n$ with distinct indexes.

### 3.1.4 $A_{3}$ cubic surfaces

The tangent cone at the singularity is the union of two planes, and the intersection line of these planes is a line of $X$ which is labelled line 3 and called the edge. It has multiplicity six. One of the biplanes is labelled 12 and it contains the additional lines 1 and 2, also called rays, the other plane is labelled $1^{\prime} 2^{\prime}$ and contains the additional lines $1^{\prime}$ and $2^{\prime}$. The rays $1,2,1^{\prime}, 2^{\prime}$ each have multiplicity four, while the biplanes 12 and $1^{\prime} 2^{\prime}$ have multiplicity 12 . The above are the five lines that contain the singular point. Next, a transversal line labelled 4 intersects the edge 3. It has multiplicity
one. The plane 0 contains the lines 3 and 4 , line 3 having multiplicity two in this plane. The plane 0 has multiplicity three. There are four more line, each with multiplicity one, labelled $i j^{\prime}$ with $i, j \in\{1,2\}$. The plane that is spanned by the lines $i$ and $j^{\prime}$ is labelled $i j^{\prime}$ and the third line of intersection in this plane is naturally $i j^{\prime}$. These four planes each have multiplicity four. There are two more planes remaining: $\overline{11^{\prime} .22^{\prime}}$ containing the lines $11^{\prime}, 22^{\prime}$ and 4 , and the plane $\overline{12^{\prime} .21^{\prime}}$ containing the lines $12^{\prime}, 21^{\prime}$ and 4 . These planes have multiplicity one.

### 3.1.5 $4 A_{1}$ cubic surfaces

The four nodes of $X$ are labelled from 1 to 4 . The six lines 12, 13, 14, 23, 24, 34 called axes, each connect two of the nodes. The axes have multiplicity four. The planes $1,2,3,4$ each contain three nodes and the three axes among them. For example plane 1 contains the nodes opposite to node 1 , i.e. the nodes $2,3,4$ and the axes $23,24,34$. The multiplicity of these planes is eight. There are three transversal lines $12.34,13.24,14.23$, each intersecting two of the axes and not touching the nodes. They have multiplicity one. The planes $12,13,14,23,24,34$ each contain the corresponding axis with multiplicity two and one of the transversals with multiplicity one. For example the plane 12 contains the lines 12 and 12.34 . The multiplicity of these planes is two. There is one more plane labelled 1234 having multiplicity one and containing the three transversals.

### 3.1.6 $2 A_{2}$ cubic surfaces

There is a line called the axis joining the two singular points. It is labelled 0 , and has multiplicity nine. Three additional lines, labelled $1,2,3$, go through the first singular point only, and similarly the lines labelled 4, 5, 6 go through the second singular point only. These six lines are called rays and they have multiplicity three. These are all the lines in $X$. The plane 0 is the common biplane of the two singular points, and it contains the line 0 only with multiplicity three. The plane 0 has multiplicity six. The plane labelled 7 is the other biplane of the first singular point, and it contains the lines 1,2 and 3 . Similarly, plane 8 is the other biplane of the second singular point and it contains the lines 4,5 and 6 . The planes 7 and 8 have multiplicity six. Finally, the plane 14 contains the lines 1,4 and 0 , the plane 25 contains the lines 2,5 and 0 and the plane 36 contains
the lines 3,6 and 0 . These planes have multiplicity nine.

### 3.2 Plane Quintic and the (2,3)-curve

Let $X$ be a cubic threefold in $\mathbb{P}^{4}$ which has at least one singularity of type $A_{n}$ or $D_{4}$ and contains isolated singularities only. Let the point $Q$ be a distinguished singularity of type $A_{n}$ or $D_{4}$ on $X$. Then the projection $\rho$ to $\mathbb{P}^{3}$ through the point $Q$ defines a birational map from the blow-up of $X$ at $Q$ onto $\mathbb{P}^{3}$. This birational map is in fact the blow-up of $\mathbb{P}^{3}$ along the curve $C$, introduced in §2.1. The curve $C$ is a complete intersection of type $(2,3)$ and is the image along the projection $\rho$ of all the lines that go through $Q$ and are contained in $X$. By theorem 2.1.18 the singularities of $C$ are in bijection with the singularities of $\mathrm{Bl}_{Q} X$ and this bijection preserves singularity type.

Next, let's fix some line $L$ contained in $X$ that does not go through $Q$ or any other singularity and is not contained in any plane that may be contained in $X$. To be more precise, we need $L$ to be non-special in the sense of [CML09, §3.2]. The two dimensional subspaces $\mathbb{P}^{2}$ of $\mathbb{P}^{4}$ containing the line $L$ can be parameterized by the projective plane $\mathbb{P}^{2}$. Let's denote this parameter space by $\Pi$. Then a point $V \in \Pi$ represents a 2 -space in $\mathbb{P}^{4}$ containing $L$. The intersection $X \cap V$ has to be a degree three curve, since $X$ is a cubic hypersurface. This intersection already contains the line $L$, therefore other than $L$ it has to be a degree two curve, i.e. either a conic curve or two lines. Let's denote by $D$ the set of points $V \in \Pi$ that represent 2 -spaces in $\mathbb{P}^{4}$ such that the intersection $X \cap V$ consists of $L$ and two other lines. We know that $D$ is a quintic curve in $\Pi=\mathbb{P}^{2}$, and the singularities of $D$ are in bijection with the singularities of $X$ and this bijection respects singularity type (see [CML09, Prop. 3.6 and its proof]). Let's denote by $R$ the point of $\Pi$ that corresponds to the 2 -space that is the span of the line $L$ and the singular point $Q$. Then $R \in D$ and $R$ has the same singularity type in $D$ as $Q$ in $X$, i.e. it is either a double point of $D$ of type $A_{n}$ or a triple point of type $D_{4}$.

We can construct a double cover of the curve $D$ in the following way. Let $\widetilde{D}$ be the curve in the Fano scheme of the lines of $X$ whose points represent lines of $X$ intersecting $L$ (but $L \notin \widetilde{D}$ ). Then a point $L_{1} \in \widetilde{D}$ is a line of $X$ that spans a 2-space $V$ together with $L$, since $L$ and $L_{1}$ intersect. As both $L$ and $L_{1}$ are in the intersection $X \cap V$, this intersection must be three lines ( $L, L_{1}$ and some
$L_{2}$ ), therefore $V \in D$. Thus we can define a map $\pi: \widetilde{D} \rightarrow D$ sending the line $L_{1}$ to the 2-space $V$. This is a double cover, since the line $L_{2}$ is also mapped to $V$ and $L_{1}$ and $L_{2}$ are the only lines that are mapped to $V$. By [CML09, Prop. 3.6] $\pi$ is étale, i.e. $L_{1}$ and $L_{2}$ are always different. We can normalize both curves $D$ and $\widetilde{D}$ and obtain the commutative diagram

where $\hat{\pi}$ is an étale double cover of smooth, possibly disconnected curves and the vertical arrows are the desingularizations. In the remaining part of this section we assume that $D$ is irreducible, which also implies that $N D$ is connected.

### 3.2.1 Trigonal construction. The $A_{n}$ case.

In this subsection we assume that $Q$ is an $A_{n}$ singularity of the cubic threefold $X$.

Proposition 3.2.2. For a cubic threefold $X$ with an $A_{n}$ singularity (and possibly other isolated singularities), and an irreducible discriminant curve $D$, the curve $N D$ is trigonal, i.e. there exists a degree three map $N D \rightarrow \mathbb{P}^{1}$.

Proof. Recall that $R$ is the point in $\Pi=\mathbb{P}^{2}$ that represents the plane spanned by the line $L$ and the point $Q$. Thus $R$ is a double point of $D$ of type $A_{n}$. Projection from $R$ gives a rational map $D \rightarrow \mathbb{P}^{1}$. Since $R$ is a double point, the map is generically $3: 1$. The normalization map is birational, so the induced map $N D \rightarrow \mathbb{P}^{1}$ is degree three.

Recillas' theorem ([Rec74], [BL04, §12.7]) says that the Prym variety belonging to an étale double cover of a trigonal, non-hyperelliptic curve is the Jacobian of a tetragonal curve. Tetragonal means that the curve has a $g_{4}^{1}$, or equivalently, that it has a degree four map onto $\mathbb{P}^{1}$. We can construct this tetragonal curve the following way. Using the above notation consider the composition

$$
\begin{equation*}
N \widetilde{D} \xrightarrow{2: 1} N D \xrightarrow{3: 1} \mathbb{P}^{1} . \tag{3.2.3}
\end{equation*}
$$

The preimage of a general point in $\mathbb{P}^{1}$ is then six points in $N \widetilde{D}$ consisting of three pairs of points where each point in a pair is mapped to the same point in $N D$. Say, if $p \in \mathbb{P}^{1}$, above $p$ we have the points $p_{1}, p_{2}, p_{3} \in N D$ and above $p_{i}$ we have the points $p_{i}^{0}, p_{i}^{1} \in N \widetilde{D}, 1 \leq i \leq 3$. A point of the tetragonal curve will be then a triple of points of $N \widetilde{D}$ (thus a point of the symmetric product $\left.(N \widetilde{D})^{(3)}\right)$, such that the three points of the triple are mapped to different points of $N D$, but are mapped to the same point of $\mathbb{P}^{1}$ (except above branch points of $N D \rightarrow \mathbb{P}^{1}$ ). In other words, from each of the three pairs of points in $N \widetilde{D}$ above a single point of $\mathbb{P}^{1}$ we pick one point to get a triple of points of $N \widetilde{D}$. In the above example a triple $\left(p_{1}^{i_{1}}, p_{2}^{i_{2}}, p_{3}^{i_{3}}\right)$ would be such a point. There are $2^{3}=8$ ways to do this, thus we get a degree eight cover of $\mathbb{P}^{1}$. It turns out that the curve that we get will have two identical components. Picking one of the components gives us the desired tetragonal curve corresponding to the double cover $\widetilde{D} \rightarrow N D$. Alternatively, we can identify complementary triples, i.e. identify $\left(p_{1}^{i_{1}}, p_{2}^{i_{2}}, p_{3}^{i_{3}}\right)$ with $\left(p_{1}^{1-i_{1}}, p_{2}^{1-i_{2}}, p_{3}^{1-i_{3}}\right)$. According to Recillas, the Jacobian of this tetragonal curve is the same as the Prym-variety of the double cover of the trigonal curve.

Remark 3.2.4. Beauville [Bea82] gives the following diagram to describe the above situation:

Here $\Sigma^{\prime}=\Sigma^{\prime \prime}$ is the tetragonal curve, $A J$ is the Abel-Jacobi map, $f: N D \xrightarrow{3: 1} \mathbb{P}^{1}, \mathrm{Nm}$ is the norm map induced by $\hat{\pi}: N \widetilde{D} \rightarrow N D, p \in \mathbb{P}^{1}$ is arbitrary and $\lambda \subset \operatorname{Pic}^{3}(N D)$ represents the $g_{3}^{1}$ of $N D$.

The following theorem generalizes a result of Collino-Murre ([CM78, Thm. 4.22]) in the case of $A_{1}$ singularities, and [CML09, Thm. 4.1] in the case of $A_{2}$ singularities. The argument we give here is inspired by that of [CMGHL15, Prop. 6.7], which gives another proof of the Collino-Murre result for cubics with an $A_{1}$ singularity. The theorem below answers affirmatively the question posed in [CML09, Rem. 4.2].

Theorem 3.2.5. For a cubic threefold $X$ having an $A_{n}$ singularity (and possibly other isolated singularities), an irreducible discriminant $D$, and a non-hyperelliptic $N D$, the tetragonal curve constructed above is isomorphic to the normalization $N C$ of the $(2,3)$-curve $C$, where $C$ is obtained from projection from an $A_{n}$ singularity.

Remark 3.2.6. By [CML09, Cor. 3.7 and its proof] for an $X$ with only one singular point, which is of type $A_{1}, \ldots, A_{6}$, the discriminant $D$ is irreducible and thus $N D$ is connected.

Proof of 3.2.5. We only need to define a birational map from $C$ to the tetragonal curve. That will also define a birational map from the normalization $N C$ to the tetragonal curve, but then a birational map between two compact smooth curves can be extended to an isomorphism.

Let's take therefore a general point $\ell \in C$ which represents a line in $X$ through the distinguished $A_{n}$ singularity $Q$. Since $\ell$ is a general point, we may assume that it is non-singular in $C$ and that it does not intersect $L$ in $X$. Because of this, $L$ and $\ell$ span some 3 -space $W$ in $\mathbb{P}^{4}$. The set of 2 -spaces contained in $W$ and containing $L$ defines a line in $\Pi$, which we denote by $w$. Since $\ell$ is a general point of $C$ and all singularities of $X$ are isolated, we may assume that $W$ does not contain any singularity of $X$ other than $Q$.

Let's consider the intersection $Y:=X \cap W$. Then $Y$ is a cubic surface and since $\ell$ is a general point we can assume that the only singularity of $Y$ is at $Q$ (i.e. $X$ and $W$ are not tangent to each other). We now show that for a general $W$ (therefore a general $\ell \in C$ ) the singularity $Q$ of $Y$ is of type $A_{1}$. Let

$$
\begin{equation*}
x^{n+1}+y^{2}+z^{2}+v^{2}=0 \tag{3.2.7}
\end{equation*}
$$

be the equation of a threefold in $\mathbb{C}^{4}$ with an $A_{n}$ singularity in the origin. Let a general hyperplane through the origin be given by the equation

$$
\begin{equation*}
v=a x+b y+c z \tag{3.2.8}
\end{equation*}
$$

Then the equation of the intersection is given by

$$
\begin{equation*}
x^{n+1}+y^{2}+z^{2}+a^{2} x^{2}+b^{2} y^{2}+c^{2} z^{2}+2 a b x y+2 a c x z+2 b c y z=0 . \tag{3.2.9}
\end{equation*}
$$

We use the method described in [All03, §2] (in particular Theorem 2.1 of [All03], attributed to Bruce and Wall) to find the singularity type at the origin. Applying the weights $\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right)$ to the variables $(x, y, z)$, we see that for general $(a, b, c)$ there are no terms with weight less than 1 and the terms of weight 1 (all terms except the first) determine an isolated singularity. Thus we have an $A_{1}$ singularity in the origin. This means that if we intersect a threefold at an $A_{n}$ singularity with a general hyperplane, we get an $A_{1}$ singularity. Of course, a general $W$ is not necessarily a general hyperplane through $Q$, since $W$ must contain the fixed line $L$. However, it is possible to choose $L$ in a way that a general $W$ containing $L$ and $Q$ intersects $X$ in an $A_{1}$ cubic surface. Indeed it is enough to find only one pair of $(W, L)$, such that $L$ is non-special, $\langle L, Q\rangle \subset W$ and $X \cap W$ is an $A_{1}$ cubic surface, because then fixing $L$ and moving $W$ in some neighborhood will not change the fact that $X \cap W$ is an $A_{1}$ cubic surface, since an open set of hyperplanes containing $Q$ intersect $X$ in an $A_{1}$ cubic surface, as was shown above. It is for dimension reasons why there must be a pair ( $W, L$ ) as given above: by [CML09, Lemma 3.9] a general $L$ is non-special, therefore there can only be a one dimensional variety of special lines in $X$ (lines that cannot be picked as $L$ ). There is however a three dimensional family of hyperplanes $W$ through $Q$ intersecting $X$ in an $A_{1}$ cubic surface, and in each $W$ there are finitely many lines of $X$ not touching $Q$. These lines make up a two dimensional family, because each line belongs to a one dimensional family of hyperplanes containing the line and $Q$. Therefore among these lines there has to be a non-special line that we can choose to be $L$. The above gives that we can fix $L$ such that for a general $W$ (and thus a general $\ell \in C$ ) $Y=X \cap Q$ is a cubic surface with one $A_{1}$ singularity.

Recall from §3.1.2 that a cubic surface with an ordinary double point contains 21 lines with the following incidence relations. The lines $l_{1}, l_{2}, \ldots, l_{6}$ go through the singular point. The plane determined by the lines $l_{i}$ and $l_{j}$ cuts out a third line $l_{i j}$, giving 15 more lines for $1 \leq i<j \leq 6$. Then $l_{i}$ meets $l_{r s}$ if and only if $i=r$ or $i=s$, and $l_{i j}$ meets $l_{r s}$ if and only if $i, j, r, s$ are all different.

In the cubic surface $Y$ we already have two lines, one is $L$ that does not meet $Q$, the other is $\ell$ that does. We can therefore identify $L$ as the line $l_{12}$ of the cubic surface, while $\ell$ will be identified with $l_{6}$. Now the 3 -space $W$ determines the line $w$ in the plane $\Pi$. The line $w$ intersects the double point $R$ (because $Q \in W$ ) and in general it intersects the quintic $D$ in three additional points. The
double point $R$ and the three additional points represent the planes of $W$ containing $L$ and meeting $Y$ in three lines (and not a line and a conic curve). The point $R$ represents the plane that is the span of $Q$ and $L=l_{12}$. Thus this plane cuts out the lines $l_{12}, l_{1}, l_{2}$ from $Y$. The three additional intersection points of $w$ and $D$ give three planes in $W$ that cut out three line triples in $Y$, where in each triple one of the lines is $l_{12}$. To see which are the other lines in the triples we enumerate the lines in $Y$ that intersect $l_{12}$ other than $l_{1}, l_{2}$. These lines are $l_{34}, l_{35}, l_{36}, l_{45}, l_{46}, l_{56}$. The three pairs that determine three planes are

$$
\begin{equation*}
\left(l_{34}, l_{56}\right),\left(l_{35}, l_{46}\right),\left(l_{36}, l_{45}\right), \tag{3.2.10}
\end{equation*}
$$

since $l_{i j}$ intersects $l_{r s}$ if and only if the indexes are distinct. Thus in the double cover $\widetilde{D} \rightarrow D$, the line $l_{34} \in \widetilde{D}$ for example is mapped to the point of $D$ that represents the plane spanned by $l_{34}$ and $l_{56}$, and so is the line $l_{56}$.

Our original goal in the proof was to find a point of the tetragonal curve that we map the point $\ell \in C$ to. Now to give a point of the tetragonal curve means that we have to pick one line $l_{i j}$ from each of the pairs in (3.2.10). Our choice cannot be arbitrary, because it has to move continuously with the point $\ell \in C$ and we also want to stay on one of the components of the curve obtained in Recillas' construction. Thus from each pair of lines we pick the one that intersects $l_{6}$, i.e. $l_{56}$ from the first pair, $l_{46}$ from the second and $l_{36}$ from the third. Thus we have defined a map from an open set of $C$ to the tetragonal curve. It is clear that this map is not constant.

Notice that the lines $l_{3}, l_{4}$ and $l_{5}$ of $Y$ are also points of $C$ and they would define the same 3space $W$ and thus the same line $w \subset \Pi$. They then also give the same three additional intersection points on $w \cap D$ and thus the same three pairs of lines as in (3.2.10). However, they will give different points on the tetragonal curve, because of our convetion of how we pick the three lines from the three pairs of lines. This is the reason why the map defined above is injective and therefore birational.

### 3.2.2 Hyperelliptic construction. The $D_{4}$ case.

In this subsection we assume that the distinguished singularity $Q$ is a $D_{4}$ singularity of the cubic threefold $X$, and that the discriminant $D$ is irreducible, which also implies that $N D$ is connected.

Proposition 3.2.11. For a cubic surface $X$ with a $D_{4}$ singularity (and possibly other isolated singularities), and an irreducible discriminant $D$, the curve $N D$ is hyperelliptic, i.e. there exists a degree two map $N D \rightarrow \mathbb{P}^{1}$.

Proof. The proof is similar to that of Proposition 3.2.2. The difference is that $R$ is a triple point of $D$, therefore a general line passing through it has two residual intersections with $D$. Thus the map $N D \rightarrow \mathbb{P}^{1}$ has degree two.

Mumford's theorem ([Mum74, §7]) says that the Prym variety of an étale double cover of a hyperelliptic smooth curve is the Jacobian of a hyperelliptic curve or the product of two such. The hyperelliptic construction gives the curve whose Jacobian is the same as the Prym of the double cover, and it goes as follows. Similarly to the trigonal construction, we consider the composition

$$
\begin{equation*}
N \widetilde{D} \xrightarrow{2: 1} N D \xrightarrow{2: 1} \mathbb{P}^{1} . \tag{3.2.12}
\end{equation*}
$$

Above a general point of $\mathbb{P}^{1}$ there are two points of $N D$ and four points, or two pairs of points, of $N \widetilde{D}$. From each pair of points we pick one to get a point of the newly created curve. There are four ways to do this, so the new curve has four points above a general point of $\mathbb{P}^{1}$. The new curve is a subvariety of the symmetric product $(N \widetilde{D})^{(2)}$. The point $(p, q) \in(N \widetilde{D})^{(2)}$ is a point of the new curve if and only if $p$ and $q$ are mapped to different points of $N D$ and the same point of $\mathbb{P}^{1}$ (except over branch points of $N D \rightarrow \mathbb{P}^{1}$ ). According to Mumford the newly constructed curve is either hyperelliptic or the disjoint union of two hyperelliptic curves.

Remark 3.2.13. As in the case of the trigonal construction (see remark 3.2.4) we have the following
diagram to describe the above situation [Bea82]:

Here $\Sigma$ is the newly constructed curve, $A J$ is the Abel-Jacobi map, $f: N D \xrightarrow{2: 1} \mathbb{P}^{1}, \mathrm{Nm}$ is the norm map induced by $\hat{\pi}: N \widetilde{D} \rightarrow N D, p \in \mathbb{P}^{1}$ is arbitrary and $\lambda \subset \operatorname{Pic}^{2}(N D)$ represents the $g_{2}^{1}$ of $N D$.

The following is the $D_{4}$-version of theorem 3.2.5:
Theorem 3.2.14. For a cubic threefold $X$ with a $D_{4}$ singularity (and possibly other isolated singularities), and an irreducible discriminant $D$, the curve constructed above is isomorphic to the normalization $N C$ of the (2,3)-curve $C$, where $C$ is obtained from projection from a $D_{4}$ singularity. Remark 3.2.15. By [CML09, Cor. 3.7] for an $X$ with only one singular point which is of type $D_{4}$, the discriminant $D$ is irreducible and thus $N D$ is connected.

Proof of 3.2.14. The proof follows the ideas of the proof of Theorem 3.2.5. Again, it is enough to construct a birational map between the curve $C$ and the curve arising from the hyperelliptic construction. If we pick a general point of $C$, that gives us a line $\ell$ in $X$ passing through $Q$, a threespace $W$ (the span of $L$ and $\ell$ ), and a line $w$ in $\Pi$ passing through $R$. If we intersect a threefold at a $D_{4}$ singularity with a general hyperplane, we get an $A_{2}$ singularity in the intersection. To see this let's take the standard form of a $D_{4}$ singularity at the origin of $\mathbb{C}^{4}$ :

$$
\begin{equation*}
x^{3}+x y^{2}+z^{2}+v^{2}=0 . \tag{3.2.16}
\end{equation*}
$$

The equation of a general hyperplane is given by

$$
\begin{equation*}
y=a x+b z+c v . \tag{3.2.17}
\end{equation*}
$$

Then the intersection becomes

$$
\begin{equation*}
x^{3}+a^{2} x^{3}+b^{2} x z^{2}+c^{2} x v^{2}+2 a b x^{2} z+2 a c x^{2} v+2 b c x z v+z^{2}+v^{2}=0 . \tag{3.2.18}
\end{equation*}
$$

Applying the weights $\left(\frac{1}{3}, \frac{1}{2}, \frac{1}{2}\right)$, we see that all terms have weight $\geq 1$ and for general $a$ the terms having weight 1 (i.e. $x^{3}+a^{2} x^{3}+z^{2}+v^{2}$ ) define an isolated singularity. Therefore the singularity has type $A_{2}$. As in the proof of Theorem 3.2.5, we can find a non special line $L$, such that for a general $W$ (and thus a general $\ell \in C$ ) $Y:=X \cap W$ is a cubic surface with a single $A_{2}$ singularity.

Recall from $\S 3.1 .3$ that a cubic surface with an $A_{2}$ singularity has 15 lines, six of which pass through the singular point. These are labelled as $l_{1}, l_{2}, \ldots, l_{6}$. There are nine lines labelled $l_{i j}$, with $i \in\{1,2,3\}, j \in\{4,5,6\}$. The lines $l_{1}, l_{2}, l_{3}$ are coplanar meeting at the singular point, and similarly the lines $l_{4}, l_{5}, l_{6}$ are coplanar meeting at the singular point. The lines $l_{i}, l_{j}, l_{i j}$ are coplanar for $i \in\{1,2,3\}, j \in\{4,5,6\}$. Finally the lines $l_{i j}, l_{k l}, l_{m n}$ are coplanar if and only if $i, j, k, l, m, n$ are distinct.

We can identify the line $\ell$ with $l_{6}$ of $Y$ and the non-special line $L$ with $l_{14}$. Then the plane spanned by $L$ and the point $Q$ intersects $X$ in the lines $L=l_{14}, l_{1}, l_{4}$. The line $w \subset \Pi$ intersects $D$ in two additional points besides $R$. These intersection points correspond to two planes in $W$ containing $L$ but not $Q$ and intersecting $X$ in three lines. These two planes intersect $X$ in the lines $L=l_{14}, l_{25}, l_{36}$ and $L=l_{14}, l_{26}, l_{35}$, respectively. In the map $\widetilde{D} \rightarrow D \rightarrow \mathbb{P}^{1}$ the line $w$ represents a point $\xi$ in $\mathbb{P}^{1}$, the two intersection points (besides $R$ ) $\eta_{1}$ and $\eta_{2}$ of $w$ with $D$ are the points above $\xi$, while the lines $l_{25}, l_{36}$ represent points of $\widetilde{D}$ above $\eta_{1}$ and the lines $l_{26}, l_{35}$ represent points of $\widetilde{D}$ above $\eta_{2}$. To pick a point of the hyperelliptic construction we pick $l_{36}$ from the pair of points above $\eta_{1}$ and we pick $l_{26}$ from the pair of points above $\eta_{2}$, that is we pick the lines that intersect $\ell=l_{6}$. Notice that besides $l_{6}$ there are three other lines in $Y$ that come from different points of $C$, namely the lines $l_{2}, l_{3}, l_{5}$. These lines determine the same line $w \subset \Pi$, and the same intersection points $\eta_{1}, \eta_{2}$, however they pick different lines from the two pairs of lines $l_{25}, l_{36}$ and $l_{26}, l_{35}$. That is why the rational map we created from $C$ to the hyperelliptic construction is injective. Also, it is clearly non-constant, therefore it is birational.

### 3.3 Generalized Intermediate Jacobians of Singular Cubic Threefolds

In $\S 2.3$ and $\S 2.4$ we desingularized a cubic threefold by successive blow-ups at singular points, before we could talk about its intermediate Jacobian. In this section we consider degenerate intermediate Jacobians of cubic threefolds with certain types of isolated singularities. Degenerate intermediate Jacobians are limit intermediate Jacobians of 1-parameter degenerations $\mathcal{X} \rightarrow \Delta$ of cubic threefolds, where $\Delta$ is the unit disk in $\mathbb{C}$, and the fibers are smooth cubic threefolds on $\Delta \backslash\{0\}$. Any such degeneration can be filled in with a semi-stable cubic threefold above $0 \in \Delta$, which means that we only have to consider cubic threefolds with at worst $A_{k}, k \leq 5$ or $D_{4}$ singularities or the chordal cubic. The latter is not treated in this paper, although we recall from [Co82] that degenerations to the chordal cubic give rise to genus five hyperelliptic Jacobians. For a computation on the stability of the cubic threefold we refer to [All03], for a brief summary see [CMGHL15, Thm. 1.1]. By a result due to Mumford, the intermediate Jacobian for a smooth cubic threefold is isomorphic to the Prym variety of the connected étale double cover of the plane quintic introduced above. Thus taking limits of intermediate Jacobians of 1-parameter degenerations is equivalent to taking degenerations of Prym varieties along 1-parameter families of unramified double covers of plane quintics ([CML09, §5.1]).

If the double cover $\widetilde{D} \rightarrow D$ at the center of a 1-parameter degeneration of covers has worse than node singularities, we can perform a stable reduction to replace the fiber at the center with a double cover that only has nodes. In this case the new 1-parameter family above $\Delta \backslash\{0\}$ only differs from the previous one by a finite base change, so the limit Prym variety is the same. To perform a stable reduction on an $A_{2 k+1}, k \geq 1$ singularity $p \in D$, we blow up $D$ at $p k$-times to normalize it and attach a hyperelliptic, genus- $k$ tail $T$ at the two points of $\mathrm{Bl}_{p}^{(k)} D$ that are above $p$. Thus we replace an $A_{2 k+1}$ singularity with two nodes, the attachment points of $T$ and $\mathrm{Bl}_{p}^{(k)} D$. In case of an $A_{2 k}, k \geq 1$ singularity, similarly we have to blow $D$ up $k$-times and add a hyperelliptic, genus- $k$ tail, but since there is only one point in $\mathrm{Bl}_{p}^{(k)} D$ above $p$, we attach the blow-up to $T$ at only one point, which then becomes a node of the stable reduction. In case of a $D_{4}$ singularity,
since in two dimensions such a point is a triple point, the elliptic tail $T$ will be attached at the three points of $\mathrm{Bl}_{p} D$ that are above $p$. After dealing with the singularities, if there are genus zero irreducible components with less than three marked points (connections with other components), we have to collapse such components to a point. As we perform the stable reduction on $D$ we have to do the same on the double cover $\widetilde{D}$ by adding the same hyperelliptic tails twice, since each singularity $p \in D$ has two preimages along $\widetilde{D} \rightarrow D$. The properties of the marked points used to attach the tail to the rest of the curve are summarized in [CMGHL15, p. 25], and for more details see [Has00].

The Jacobian of a curve $C$ with nodes can be defined as the group of line bundles on $C$ with multidegree 0 , meaning the degree must be 0 on all irreducible components. Equivalently, it can be defined as the limit of Jacobians of 1-parameter degenerations of smooth curves. Such a Jacobian is a semiabelian variety which can be given by a short exact sequence

$$
\begin{equation*}
1 \rightarrow H^{1}(\Gamma, \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{C}^{*} \rightarrow J C \rightarrow J(N C) \rightarrow 0 \tag{3.3.1}
\end{equation*}
$$

where $\Gamma$ is the dual graph of $C, \mathbb{C}^{*}$ is the multiplicative group of $\mathbb{C}$, and $N C$ is the normalization (or desingularization) of $C$. Thus $J C$ is the extension of the principally polarized abelian variety $J(N C)$ (the compact part) by some torus $\left(\mathbb{C}^{*}\right)^{n}$ (the non-compact part). We can thus give a Jacobian by specifying the compact and non-compact parts, as well as an element of the extension $\operatorname{group} \operatorname{Ext}\left(J(N C), H^{1}(\Gamma, \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{C}^{*}\right)$. The latter is equivalent to giving a homomorphism $H_{1}(\Gamma, \mathbb{Z}) \rightarrow$ ${ }^{t} J(N C)$, where ${ }^{t} J(N C)$ is the dual of the compact part, and $H_{1}(\Gamma, \mathbb{Z})$ is the character group or dual of the non-compact part. This map is defined as follows: we identify ${ }^{t} J(N C)$ with $J(N C)$ through the principal polarization, then any edge $e$ in a cycle is mapped to $t(e)-s(e)$, where $t(e)$ and $s(e)$ are points that are the results of the desingularization of the node represented by $e, t(e)$ is located on the target component of $e$ and $s(e)$ is located on the source component of $e$ (see [ABH02, §1.1]).

Now let $\widetilde{D} \rightarrow D$ be an étale double cover of nodal curves. We can define its Prym variety by taking limits of Prym varieties of 1-parameter degenerations of étale double covers of smooth
curves, or equivalently by setting

$$
\begin{equation*}
P_{\widetilde{D} / D}=\operatorname{Ker}(1+\iota)_{0}=\operatorname{Im}(1-\iota) \tag{3.3.2}
\end{equation*}
$$

where $\iota: J \widetilde{D} \rightarrow J \widetilde{D}$ is induced by the fixed point free involution $\iota: \widetilde{D} \rightarrow \widetilde{D}$, which is induced by the étale double cover $\widetilde{D} \rightarrow D$. Such a Prym variety is a semiabelian variety which can be given by a short exact sequence

$$
\begin{equation*}
1 \rightarrow H^{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} \otimes_{\mathbb{Z}} \mathbb{C}^{*} \rightarrow P_{\widetilde{D} / D} \rightarrow P_{N \widetilde{D} / N D} / G \rightarrow 0 \tag{3.3.3}
\end{equation*}
$$

where $\widetilde{\Gamma}$ is the dual graph of $\widetilde{D}, H^{1}(\widetilde{\Gamma}, \mathbb{Z})^{-}$is the -1-eigenspace of $H^{1}(\widetilde{\Gamma}, \mathbb{Z})$ with respect to $\iota: \widetilde{\Gamma} \rightarrow \widetilde{\Gamma}$, the involution induced by $\iota: \widetilde{D} \rightarrow \widetilde{D}$. The curves $N \widetilde{D}$ and $N D$ are normalizations and $G \subset P_{N \widetilde{D} / N D}$ is a finite group that will be described later. The dual or the character group of the non-compact part is

$$
\begin{equation*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}=H_{1}(\widetilde{\Gamma}, \mathbb{Z}) / H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} \tag{3.3.4}
\end{equation*}
$$

where $H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$is the +1 -eigenspace of $H_{1}(\widetilde{\Gamma}, \mathbb{Z})$. Equivalently $H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}$can also be defined as the image of the map

$$
\begin{align*}
\pi^{-}: H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & \longrightarrow H_{1}\left(\widetilde{\Gamma}, \frac{1}{2} \mathbb{Z}\right)  \tag{3.3.5}\\
h & \longmapsto \frac{1}{2}(h-\iota(h)), \tag{3.3.6}
\end{align*}
$$

see $[\mathrm{ABH} 02, \mathrm{p} .10]$. It is possible to choose a basis $\left\langle u_{1}, \ldots, u_{k}, v_{1}, \ldots, v_{l}, w_{1}, \ldots, w_{2 m}\right\rangle$ of $H_{1}(\widetilde{\Gamma}, \mathbb{Z})$ such that $\iota: H_{1}(\widetilde{\Gamma}, \mathbb{Z}) \rightarrow H_{1}(\widetilde{\Gamma}, \mathbb{Z})$ is the identity on $\left\langle u_{i}\right\rangle_{i=1}^{k}$, is multiplication by -1 on $\left\langle v_{i}\right\rangle_{i=1}^{l}$ and
interchanges $w_{2 i-1}$ and $w_{2 i}$ for $1 \leq i \leq m$. Then we have

$$
\begin{gather*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}=\left\langle u_{1}, \ldots, u_{k}, w_{1}+w_{2}, \ldots, w_{2 m-1}+w_{2 m}\right\rangle  \tag{3.3.7}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-}=\left\langle v_{1}, \ldots, v_{l}, w_{1}-w_{2}, \ldots, w_{2 m-1}-w_{2 m}\right\rangle  \tag{3.3.8}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}=\operatorname{Im}\left(\pi^{-}\right)=\left\langle v_{1}, \ldots, v_{l}, \frac{1}{2}\left(w_{1}-w_{2}\right), \ldots, \frac{1}{2}\left(w_{2 m-1}-w_{2 m}\right)\right\rangle  \tag{3.3.9}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} / H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} \cong(\mathbb{Z} / 2 \mathbb{Z})^{m}  \tag{3.3.10}\\
(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=\left\langle 2 u_{1}, \ldots, 2 u_{k}, w_{1}+w_{2}, \ldots, w_{2 m-1}+w_{2 m}\right\rangle  \tag{3.3.11}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}=H_{1}(\widetilde{\Gamma}, \mathbb{Z}) / H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}= \\
\left(H_{1}(\widetilde{\Gamma}, \mathbb{Z}) /(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})\right) /\left(H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} /(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})\right)=  \tag{3.3.12}\\
\left(H_{1}(\widetilde{\Gamma}, \mathbb{Z}) /(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})\right) /(\text { Torsion }) .
\end{gather*}
$$

By part 1 of [ABH02, Lemma 1.4] the extension homomorphism of (3.3.3) can be defined by the last column of the diagram:

where

$$
\begin{equation*}
K=\frac{{ }^{t} J(N \widetilde{D}) /(1+\iota)^{t} J(N \widetilde{D})}{c^{\prime}\left(\operatorname{Torsion}\left(H_{1}(\widetilde{\Gamma}, \mathbb{Z}) /(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})\right)\right)} \tag{3.3.14}
\end{equation*}
$$

$c$ is the extension homomorphism of $J \widetilde{D}, c^{\prime}$ and $c^{[-]}$are induced from $c$ and the rightmost horizontal map of the first row is factoring by the torsion group. To get the element in the upper right corner we used (3.3.12). If we dualize the second row and add the dualization as an extra row, delete the
first column, then using [ABH02, Prop. 1.5] we get the diagram

Here $\gamma$ is the extension map of $J \widetilde{D}$ giving $\gamma(e)=t(e)-s(e)$ for a cycle $e$, as was defined earlier. The maps between the last two rows come from the polarizations, $\Theta$ being the principal polarization of $J(N \widetilde{D})$, and $\Xi$ being the principal polarization of $P_{N \widetilde{D} / N D}$. By a well known property of Prym varieties

$$
\begin{equation*}
\left.\Theta\right|_{P_{N \tilde{D} / N D}} \cong 2 \cdot \Xi . \tag{3.3.16}
\end{equation*}
$$

The composition $H_{1}(\widetilde{\Gamma}, \mathbb{Z}) \rightarrow H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}$of the second row is in fact $\pi^{-}$of (3.3.5). For the finite group $G$ we have $G \cong(\mathbb{Z} / 2 \mathbb{Z})^{d}$, where $0 \leq d \leq k, k$ being the dimension of the subspace of $H_{1}(\widetilde{\Gamma}, \mathbb{Z})$ on which $\iota$ is the identity. Then some diagram chasing gives:

Proposition 3.3.17. If $H_{1}(\widetilde{\Gamma}, \mathbb{Z}) /(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}$, (i.e. $\left.(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}\right)$, then the Prym variety is an extension

$$
\begin{equation*}
1 \rightarrow H^{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} \otimes_{\mathbb{Z}} \mathbb{C}^{*} \rightarrow P_{\tilde{D} / D} \rightarrow P_{N \tilde{D} / N D} \rightarrow 0 \tag{3.3.18}
\end{equation*}
$$

with extension data given by the map

$$
\begin{equation*}
\gamma^{[-]}: H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} \rightarrow P_{N \widetilde{D} / N D} \tag{3.3.19}
\end{equation*}
$$

which is defined as follows. For any $z \in H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}$, one has $2 z \in H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} \subseteq H_{1}(\widetilde{\Gamma}, \mathbb{Z})$, and we
set $\gamma^{[-]}(z):=\gamma(2 z)$; i.e.,

$$
\begin{equation*}
\sum n_{i} e_{i} \mapsto \mathcal{O}_{N D}\left(\sum 2 n_{i}\left(t\left(e_{i}\right)-s\left(e_{i}\right)\right)\right) \tag{3.3.20}
\end{equation*}
$$

Note that here, we may have $n_{i} \in \frac{1}{2} \mathbb{Z}$, under the natural identification of $H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}$with the image of the map $H_{1}(\widetilde{\Gamma}, \mathbb{Z}) \rightarrow H_{1}\left(\widetilde{\Gamma}, \frac{1}{2} \mathbb{Z}\right)$, given by $z \mapsto \frac{1}{2}(z-\iota z)$.

## Chapter 4

## Geometric Realization of Strata in the Boundary of the Intermediate Jacobian Locus

### 4.1 Irreducible Quintic

In this section $X$ is a cubic threefold with isolated singularities, $\ell \subset X$ is a non-special line (as defined in [CML09, $\S 3.2]$ ), and the discriminant curve $D$ is a plane quintic that we assume to be irreducible. We also assume that the double cover $\widetilde{D}$ is irreducible. Note that for cubic threefolds with a unique singularity of type $A_{k}, k \leq 6$ or $D_{4}$, the discriminant is automatically irreducible [CML09, Cor. 3.7 and its proof].

### 4.1.1 $\quad A_{1}$ cubic threefolds

For completeness, here we review the case of cubic threefolds with an $A_{1}$ singularity. The result is essentially due to [CM78] and the argument we give here follows [CMGHL15, Thm. 6.4]. We include the proof since it helps to motivate the approach we take in other, more complicated cases.

Let $X$ be a cubic threefold with a unique singular point, which is an $A_{1}$ singularity. Let $\widetilde{D} \rightarrow D$ be the étale double cover of the plane quintic. Then $D$ has one $A_{1}$ singularity $p$, and recall that $D$ is automatically irreducible. Above $p$ the two nodes of $\widetilde{D}$ are $p^{+}$and $p^{-}$. Both $D$ and $\widetilde{D}$ are
irreducible. The dual graph $\Gamma$ of $D$ is therefore

$$
\begin{equation*}
\stackrel{v}{\bigcirc} \tag{4.1.1}
\end{equation*}
$$

where $v$ represents the only irreducible component of $D$ and $e$ represents the node $p$. The dual graph $\widetilde{\Gamma}$ of $\widetilde{D}$ is

where $v$ represents the only irreducible component of $\widetilde{D}$ and $e^{+}$and $e^{-}$represent the nodes $p^{+}$and $p^{-}$respectively. Using results from page 42 we have

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e^{+}, e^{-}\right\rangle  \tag{4.1.3}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e^{+}+e^{-}\right\rangle  \tag{4.1.4}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e^{+}-e^{-}\right\rangle  \tag{4.1.5}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e^{+}-e^{-}\right)\right\rangle . \tag{4.1.6}
\end{align*}
$$

Since $(1+\iota)\left(e^{+}\right)=(1+\iota)\left(e^{-}\right)=e^{+}+e^{-}$, we have $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. Therefore the Prym-variety of $\widetilde{D} \rightarrow D$ is given by

$$
\begin{equation*}
1 \rightarrow H^{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} \otimes_{\mathbb{Z}} \mathbb{C}^{*} \rightarrow P_{\widetilde{D} / D} \rightarrow P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.7}
\end{equation*}
$$

and the intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow P_{N \widetilde{D} / N D} \rightarrow 0 \tag{4.1.8}
\end{equation*}
$$

where the extension data is

$$
\begin{equation*}
g \mapsto \mathcal{O}_{N \widetilde{D}}\left(p_{1}^{+}-p_{2}^{+}-p_{1}^{-}+p_{2}^{-}\right) \tag{4.1.9}
\end{equation*}
$$

obtained from proposition 3.3 .17 . Here $p_{1}^{+}$and $p_{2}^{+}$are the points on $N \widetilde{D}$ that we receive from
blowing up the point $p^{+}$and similarly for the points $p_{1}^{-}, p_{2}^{-}, p^{-}$.
We want to show that $N D$ is non-hyperelliptic. Since $D$ is planar degree five with a node, $N D$ is genus five. Let's consider all conic curves in the plane of $D$ that go through the node of $D$. Since five points determine a conic and one is fixed at the node, we can choose such a conic by picking four points on the plane. This gives us a choice of dimension eight, however, once we pick the four points and thus the conic, if we move the points around on the conic, the conic will not change. Therefore there is a four dimensional family of conics passing through the node of $D$. The conic and $D$ must have 10 intersection points, but two of these are at the node. This gives us a base point free $g_{8}^{4}$ on $D$ and $N D$, which means $N D$ can be embedded into $\mathbb{P}^{4}$ as a degree 8 curve. Thus it cannot be hyperelliptic by standard algebraic curve theory. Alternatively, since $g(N D)=5$ and $N D$ has a base point free $g_{3}^{1}$ (which must be complete by Clifford's Theorem), $N D$ is non-hyperelliptic by [ACGH85, p. 13]. This in fact works for all genus at least three.

Since the curve $N D$ is genus five, non-hyperelliptic and trigonal, by Theorem 3.2.5 the Prymvariety $P_{N \widetilde{D} / N D}$ is the Jacobian of the (2,3)-curve $C$, which is smooth (Theorem 2.1.18) and genus four. From the proof of Theorem 2.1.1, $C$ is the intersection of the quadric $Q=0$ and the cubic $F=0$, where $Q$ gives the tangent cone to the node of $X$ if considered as a polynomial in the open affine $\mathbb{C}^{4}$, and gives the projectivization of the tangent cone if considered as a homogeneous polynomial in $\mathbb{P}^{3}$. For an $A_{1}$ singularity the tangent cone is a quadric cone whose projectivization is a smooth quadric. Under the indentification of the Prym of $N \widetilde{D} \rightarrow N D$ with the Jacobian of $C$ the extension data is given by the difference of the two $g_{3}^{1}$ 's on the $(2,3)$-curve (see [CMGHL15, $\S 6.1$ and Theorem 6.4]). The two $g_{3}^{1}$ 's come from the two rulings of the smooth quadric that contains $C$.

To summarize, the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J C \rightarrow 0 \tag{4.1.10}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto N \otimes \hat{N} \in J C, \tag{4.1.11}
\end{equation*}
$$

where $N$ and $\hat{N}$ are the two $g_{3}^{1}$ 's on C. (In Theorem 6.4 of [CMGHL15] we see $(N \otimes \hat{N})^{\otimes \pm 1}$, but that is because in fact the extension data should be in $J C / \operatorname{Aut}(J C)$. Now $\operatorname{Aut}(J C) \cong\{ \pm 1\}$, explaining the ambiguity.)

### 4.1.2 $\quad A_{2}$ cubic threefolds

This case is also covered in [CML09]. Let $X$ be a cubic threefold with a unique singular point, which is an $A_{2}$ singularity and let $\widetilde{D} \rightarrow D$ be the étale double cover of the plane quintic. Recall that $D$ is automatically irreducible. Then the (2,3)-curve is smooth and genus four, while $D$ has an $A_{2}$ singularity $p$. This means we need to perform a stable reduction. If the result is the cover $\widetilde{F} \rightarrow F$, then $F$ consists of two irreducible components, one being the normalization $N D$, the other an elliptic tail $T$. The two components are attached at a node which on $N D$ rests over the point received from the blow-up of $D$ at $p$. Then the curve $\widetilde{F}$ consists of three components, two of which are identical to $T\left(T^{+}\right.$and $\left.T^{-}\right)$and the third is the normalization $N \widetilde{D}$. This gives the following dual graph $\widetilde{\Gamma}$ :

We can see that $H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-}=0$, and thus $I J(X)$ does not have a noncompact part. Therefore

$$
\begin{equation*}
I J(X)=J T \times P_{N \tilde{D} / N D}=J T \times J C, \tag{4.1.13}
\end{equation*}
$$

where $J T$ is the Jacobian of the elliptic curve $T$, and $J C$ is the Jacobian of the $(2,3)$-curve $C$. To see that $J C=P_{N \widetilde{D} / N D}$, we have to show that $N D$ is non-hyperelliptic. This can be done similar to the $A_{1}$ case, since $N D$ is genus five, just like it was genus five in the $A_{1}$ case.

### 4.1.3 $\quad A_{3}$ cubic threefolds

We now address the case of cubic threefolds with an $A_{3}$ singularity. This case is dealt with in [CMGHL15, Thm. 6.3, §6.2]; we follow the proof there, and also provide one strengthening, that
the extension data for the degeneration of the intermediate Jacobian, lying in the Jacobian of the normalization of the $(2,3)$-curve, is in fact due to the difference of points lying over the node in the (2,3)-curve; this is explained in more detail below.

With the usual notation, $D$ (automatically irreducible) now has an $A_{3}$ singularity $p$ and the (2,3)-curve $C$ has an $A_{1}$ singularity. The stable reduction $F$ consists of an elliptic tail $T$ and the normalization $N D$ which is genus four. They are attached to each other at the two nodes $p_{1}=t_{1}$ and $p_{2}=t_{2}$, where $p_{i} \in N D$ come from the blow-up of $p$ and $t_{i} \in T$. Then $\widetilde{F}$ consists of two elliptic curves $T^{+}$and $T^{-}$which are isomorphic to $T$ and the normalization $N \widetilde{D}$. The tail $T^{+}$is attached to $N \widetilde{D}$ by the two nodes $p_{1}^{+}=t_{1}^{+}$and $p_{2}^{+}=t_{2}^{+}$and similarly for $T^{-}, p_{i}^{-}$and $t_{i}^{-}$. The double cover $\widetilde{F} \rightarrow F$ then consists of a trivial cover $T^{+} \sqcup T^{-} \rightarrow T$ and the cover $N \widetilde{D} \rightarrow N D$ which is induced from $\widetilde{D} \rightarrow D$. The points $p_{i}^{ \pm} \in N \widetilde{D}$ are above $p_{i} \in N D$ and $t_{i}^{ \pm} \in T^{ \pm}$are above $t_{i} \in T$, for $i=1,2$. This arrangement gives the dual graph $\widetilde{\Gamma}$ :

For the cohomology we have

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e_{1}^{+}-e_{2}^{+}, e_{1}^{-}-e_{2}^{-}\right\rangle  \tag{4.1.15}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e_{1}^{+}-e_{2}^{+}+e_{1}^{-}-e_{2}^{-}\right\rangle  \tag{4.1.16}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e_{1}^{+}-e_{2}^{+}-e_{1}^{-}+e_{2}^{-}\right\rangle  \tag{4.1.17}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e_{1}^{+}-e_{2}^{+}-e_{1}^{-}+e_{2}^{-}\right)\right\rangle . \tag{4.1.18}
\end{align*}
$$

It is straightforward to check that $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. For the intermediate Jacobian we have

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.19}
\end{equation*}
$$

with extension data $g \mapsto\left(\mathcal{O}_{T}\left(t_{1}-t_{2}\right), \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)\right)$.
The curve $N D$ is genus four and trigonal. To prove that it is non-hyperelliptic, we proceed like in the $A_{1}$ case with some modifications. Let's take the conics in the plane of $D$ that go through the singularity of $D$ and have the same tangent there as the tangent given by the $A_{3}$ singularity. That means we can use three points to determine the conic and this gives us $6-3=3$ degrees of freedom. The intersection multiplicity of the conic and $D$ is four, therefore there has to be six other intersection points. This gives us a base point free $g_{6}^{3}$ and an embedding of $N D$ to $\mathbb{P}^{3}$ as a degree six curve. Therefore $N D$ is non-hyperelliptic by standard algebraic curve theory. Alternatively, we can use [ACGH85, p. 13]. As $N D$ is non-hyperelliptic the Prym-variety of $N \widetilde{D} \rightarrow N D$ is the Jacobian of the normalization of the (2,3)-curve, or $P_{N \tilde{D} / N D}=J(N C)$.

Next we want to find the extension data on $J(N C)$. The curve $C$ is the intersection of a singular quadric cone and a cubic surface and it has an $A_{1}$ singularity at the node of the cone. The normalization $N C$ is genus three and it is hyperelliptic, because the ruling of the cone gives a $g_{2}^{1}$ on $C$ (each line of the ruling intersects $C$ at three points, but one of these is always the node). Lines in the plane of $D$ passing through $p \in D$ give a $g_{3}^{1}$ on $N D$. One of these lines, the tangent line of the $A_{3}$ singularity $p \in D$ gives the divisor $p_{1}+p_{2}+r$ on $N D$ which belongs to the $g_{3}^{1}$. The point $r \in D$ is the fifth intersection point of the tangent line with $D$, as the intersection multiplicity at $p$ is four. Let $\tilde{r} \in N \widetilde{D}$ be one of the points above $r$. If we pick the points $\xi_{1}=p_{1}^{+}+p_{2}^{-}+\tilde{r}$ and $\xi_{2}=p_{1}^{-}+p_{2}^{+}+\tilde{r}$ on $N C$ using the trigonal construction, then the extension data becomes $p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}=\xi_{2}-\xi_{1}$ in $J(N C)$. Using that $N C$ is genus three and hyperelliptic, this is a point on the particular symmetric theta divisor $N C-N C$ (see also [CMGHL15, §6.2]).

Let's denote the node of $C$ by $\xi$. We want to prove that the points $\xi_{1}, \xi_{2} \in N C$ found above come from $\xi$ after desingularization. To see this we need to prove that the line of $X$ represented by $\xi$ is mapped to the tangent line of $p \in D$ through the projection from the non-special line $\ell$. The point $\xi$ represents the null-line of the $A_{3}$ singularity of $X$. This line together with $\ell$ spans a three-space $W$ that intersects $X$. Now $W \cap X$ is a cubic surface with an $A_{3}$ singularity in general. If we cut $X$ with a three-space in general position, the singularity becomes $A_{1}$, but now we are in the special case where the three-space $W$ contains the null-line of $A_{3}$. In general the singularity
remains $A_{3}$ in this case (it can get worse for a special three-space). According to §3.1.4 line 4 in $W \cap X$ cannot be picked as $\ell$, because in plane 0 besides line 4 , there is line 3 with multiplicity two, therefore the cover $\widetilde{D} \rightarrow D$ would not be étale. Line $11^{\prime}$ can be a good choice for $\ell$. There are only two planes containing line $11^{\prime}$, plane $11^{\prime}$ having multiplicity four and containing the singular point, and plane $11^{\prime} .22^{\prime}$ having multiplicity one and not containing the singular point. This means that the line in the plane of $D$ that corresponds to the three-space $W$ must intersect $D$ at two points and therefore it has to be the tangent line of the singular point $p$. Even the multiplicities of the planes coincide with the intersection multiplicities of the tangent line and $D$.

To summarize, the intermediate Jacobian of $X$ is given by the sequence

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0, \tag{4.1.20}
\end{equation*}
$$

with extension data $g \mapsto\left(\mathcal{O}_{T}\left(t_{1}-t_{2}\right), \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)$, where $\xi_{1}, \xi_{2} \in N C$ come from blowing up the point $\xi \in C$.

### 4.1.4 $\quad A_{4}$ cubic threefolds

This case is also covered in [CML09], see table on page 52. The $A_{4}$ case is very similar to the $A_{2}$ case. Now the $(2,3)$-curve has an $A_{2}$ singularity which lies at the node of the cone. Thus $N C$ is genus three and hyperelliptic, the $g_{2}^{1}$ coming from the ruling of the cone. The stable reduction of $\widetilde{D} \rightarrow D$ ( $D$ being automatically irreducible) gives a curve $F$ with two components, one being a genus two, hyperelliptic tail $T$, the other being the normalization $N D$, which is genus four, nonhyperelliptic and trigonal. We can see that it is non-hyperelliptic similar to the $A_{3}$ case, noting that the tangent line of a planar $A_{4}$ singularity has intersection multiplicity four with the curve at the $A_{4}$ singularity in general. The Prym-variety of the double cover of $N D$ is thus the Jacobian of $N C$. The dual graph $\widetilde{\Gamma}$ is exactly as in the $A_{2}$ case. For the intermediate Jacobian we then have

$$
\begin{equation*}
I J(X)=J T \times P_{N \tilde{D} / N D}=J T \times J(N C), \tag{4.1.21}
\end{equation*}
$$

where $T$ is genus two and hyperelliptic, $N D$ is genus four, non-hyperelliptic and trigonal and $N C$ is genus three and hyperelliptic.

### 4.1.5 $\quad A_{5}$ cubic threefolds

This is very similar to the $A_{3}$ case. Now $D$ has an $A_{5}$ singularity at $p$ and $C$ has an $A_{3}$ singularity at the node of the cone. Thus $N D$ is genus three and $N C$ is genus two and hyperelliptic. In the stable reduction the tail $T$ is genus two. We have the same configuration for $T, T^{ \pm}, p_{i}, p_{i}^{ \pm}, t_{i}, t_{i}^{ \pm}$as in the $A_{3}$ case, and the dual graph $\widetilde{\Gamma}$ is exactly the same. We also know that $t_{1}+t_{2}$ is a divisor on $T$ belonging to the $g_{2}^{1}$. The extension data also has the same format as in the $A_{3}$ case.

We need to prove that $N D$ is non-hyperelliptic. The proof is similar to the $A_{1}$ and $A_{3}$ cases. Now we consider conics in the plane that go through the $A_{5}$ singularity at p , and has the same tangent to the second degree as that given by the $A_{5}$ singularity. In other words conics that approximate the two branches of $A_{5}$ locally to degree two. This means that we are fixing three of the five points that determine a conic, so we have two points left that we can freely choose on the plane. That gives us $4-2=2$ degrees of freedom in picking a conic. Since the conic approximates both branches locally to the second degree, the intersection multiplicity of the conic and the quintic at $p$ is six. We therefore have four other intersection points that vary with the conics. This gives us a base point free $g_{4}^{2}$ and an embedding to $\mathbb{P}^{2}$ as a degree four curve. Therefore $N D$ cannot be hyperelliptic (alternatively, use [ACGH85, p. 13]). Thus we can use the trigonal construction and the Prym-variety of the double cover of $N D$ is the Jacobian of $N C$.

We want to locate the extension data on $J(N C)$. We want to prove that this is just $\xi_{2}-\xi_{1}$, where $\xi_{1}, \xi_{2}$ come from blowinp up the singularity of $C$, exactly as in the $A_{3}$ case. To see this we need to prove that the singular point $\xi$ on $C$ is mapped to the tangent line of the singularity $p$ along the projection from $\ell$. But this proof is the exact same as in the $A_{3}$ case, because a general threespace that contains the null-line of an $A_{5}$ singularity gives an $A_{3}$ singularity on the intersection surface, while for a general planar $A_{5}$ singularity the tangent line of the singularity has intersection multiplicity four with the singular point. Thus the situation is the same as in the $A_{3}$ case, and the same proof works.

As a result the intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0 \tag{4.1.22}
\end{equation*}
$$

with extension data $g \mapsto\left(\mathcal{O}_{T}\left(t_{1}-t_{2}\right), \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)$, where $T$ is genus two, hyperelliptic, $t_{1}+t_{2} \in g_{2}^{1}$, $N C$ is genus two, hyperelliptic and $\xi_{1}, \xi_{2} \in N C$ come from blowing up the singular point $\xi \in C$.

### 4.1.6 $\quad A_{6}$ cubic threefolds

This case is similar to the $A_{4}$ case. The discriminant $D$ is automatically irreducible. The intermediate Jacobian is given by

$$
\begin{equation*}
I J(X)=J T \times P_{N \tilde{D} / N D}=J T \times J(N C), \tag{4.1.23}
\end{equation*}
$$

where the tail $T$ is genus three and hyperelliptic, $N D$ is genus three, non-hyperelliptic and trigonal, and finally $N C$ is genus two and hyperelliptic. To prove that $N D$ is non-hyperelliptic we can use [ACGH85, p. 13].

Remark 4.1.24. According to Allcock (see e.g., [CMJL12, Thm. 2.1]), $X$ with an $A_{n}, n \geq 6$ singularity is semi-stable if and only if it does not contain any of the planes containing its null line. In this case $X$ degenerates (in the sense of [CMJL12, §2.1]) to the chordal cubic, and this means that $I J(X)$ should be a degeneration of a hyperelliptic Jacobian, as is the case above.

### 4.1.7 $\quad A_{7}$ cubic threefolds with irreducible discriminants

Similar to the $A_{5}$ case. Remark 4.1.24 also applies here. The curve $D$ has a unique singularity, which is $A_{7}$, therefore $N D$ is genus two and necessarily hyperelliptic. The tail $T$ is now genus three and hyperelliptic. Using the hyperelliptic construction the Prym-variety $P_{N \tilde{D} / N D}$ is the Jacobian of an elliptic curve $G$. Thus the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times J G \rightarrow 0, \tag{4.1.25}
\end{equation*}
$$

where $T$ is genus three, hyperelliptic, and $G$ is elliptic.
Suspicion: $C$ is an irreducible $(2,3)$-curve with an $A_{5}$ singularity, thus $N C$ is an elliptic curve and $G=N C$ via the hyperelliptic construction. The extension data is $g \mapsto\left(\mathcal{O}_{T}\left(t_{1}-t_{2}\right), \mathcal{O}_{N C}\left(\xi_{2}-\right.\right.$ $\left.\xi_{1}\right)$ ), where $\xi_{1}, \xi_{2}$ come from the normalization of the singularity of $C$.

### 4.1.8 $\quad A_{8}$ cubic threefolds with irreducible discriminants

Similar to the $A_{6}$ case. Remark 4.1.24 also applies here. The intermediate Jacobian is given by

$$
\begin{equation*}
I J(X)=J T \times P_{N \tilde{D} / N D}=J T \times J G, \tag{4.1.26}
\end{equation*}
$$

where the tail $T$ is genus four and hyperelliptic, $N D$ is genus two and hyperelliptic and $G$ is elliptic.
Suspicion: $C$ is an irreducible (2,3)-curve with an $A_{6}$ singularity, thus $N C$ is an elliptic curve and $G=$ NC via the hyperelliptic construction.

### 4.1.9 $\quad A_{9}$ cubic threefolds with irreducible discriminants

Similar to the $A_{5}, A_{7}$ cases. Remark 4.1.24 also applies here. Now $N D$ is elliptic, therefore the Prym of the double cover is trivial. The intermediate Jacobian:

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \rightarrow 0 \tag{4.1.27}
\end{equation*}
$$

where the tail $T$ is genus four and hyperelliptic and the extension data is $g \mapsto \mathcal{O}_{T}\left(t_{1}-t_{2}\right)$.

### 4.1.10 $\quad D_{4}$ cubic threefolds

If $X$ has one $D_{4}$ singularity, the plane quintic $D$ (automatically irreducible) has one $D_{4}$ singularity at $p$. The curve $\widetilde{D}$ is irreducible with two $D_{4}$ singularities $p^{+}$and $p^{-}$, which are the preimage of $p$ along the double cover $\widetilde{D} \rightarrow D$. The stable reduction then gives the double cover $\widetilde{F} \rightarrow F$, where $F$ has two irreducible components, one being an elliptic tail $T$, the other being the normalization $N D$. They are attached at three nodes $p_{1}=t_{1}, p_{2}=t_{2}, p_{3}=t_{3}$, where $p_{i} \in N D$ come from the blow-up of $p \in D$. The curve $\widetilde{F}$ has three components, two of which being identical to $T$ ( $T^{+}$and
$T^{-}$), one of which being the normalization $N \widetilde{D}$. We have the points $p_{i}^{ \pm}, t_{i}^{ \pm}$on $\widetilde{F}$ above the points $p_{i}, t_{i} \in F$. Then the dual graph $\widetilde{\Gamma}$ of $\widetilde{F}$ is the following:

For the cohomology we have

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e_{3}^{+}-e_{2}^{+}, e_{3}^{+}-e_{1}^{+}, e_{3}^{-}-e_{2}^{-}, e_{3}^{-}-e_{1}^{-}\right\rangle  \tag{4.1.29}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e_{3}^{+}-e_{2}^{+}+e_{3}^{-}-e_{2}^{-}, e_{3}^{+}-e_{1}^{+}+e_{3}^{-}-e_{1}^{-}\right\rangle  \tag{4.1.30}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e_{3}^{+}-e_{2}^{+}-e_{3}^{-}+e_{2}^{-}, e_{3}^{+}-e_{1}^{+}-e_{3}^{-}+e_{1}^{-}\right\rangle  \tag{4.1.31}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e_{3}^{+}-e_{2}^{+}-e_{3}^{-}+e_{2}^{-}\right), \frac{1}{2}\left(e_{3}^{+}-e_{1}^{+}-e_{3}^{-}+e_{1}^{-}\right)\right\rangle . \tag{4.1.32}
\end{align*}
$$

It is easy to check that $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. The intermediate Jacobian is an extension

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times P_{N \widetilde{D} / N D} \rightarrow 0 \tag{4.1.33}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}\left(t_{3}-t_{2}\right), \mathcal{O}_{N \widetilde{D}}\left(p_{3}^{+}-p_{2}^{+}-p_{3}^{-}+p_{2}^{-}\right)\right)  \tag{4.1.34}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}\left(t_{3}-t_{1}\right), \mathcal{O}_{N \widetilde{D}}\left(p_{3}^{+}-p_{1}^{+}-p_{3}^{-}+p_{1}^{-}\right)\right) \tag{4.1.35}
\end{align*}
$$

By Theorem 3.2.14 the Prym of $N \widetilde{D} \rightarrow N D$ is the Jacobian of the normalization $N C$. We also know that this is eiher a hyperelliptic Jacobian or the product of two such. Let's consider the singular point of $X$. It is a $D_{4}$ singularity, whose tangent cone is the union of two hyperplanes. The intersection of the two hyperplanes give a plane that contains three lines of $X$. These lines
represent the three directions that would give the three $A_{1}$ singularities in the blow up at $p$ and they give the three $A_{1}$ singularities of $C$. In fact the tangent cone when projectivized is the union of two planes and the three nodes of $C$ lie on their intersection line. Let's denote these nodes by $q_{1}, q_{2}, q_{3}$. The cubic surface in $\mathbb{P}^{3}$ then intersects the projectivized tangent cone in two elliptic curves in the two planes of the projectivized tangent cone. These two elliptic curves make up the curve $C$ and they are attached at the three nodes $q_{1}, q_{2}, q_{3}$. The normalization $N C$ is then the disjoint union of two elliptic curves with three marked points on each.

Now let's pick the point $q_{1} \in C$. It represents one of the three lines of $X$ in the intersection of the two hyperplanes that make up the tangent cone of the singular point. An easy computation shows that in general a three-space that contains such a line intersects $X$ in a cubic surface where the $D_{4}$ singularity becomes $A_{3}$. Let $W$ be the three-space spanned by the non-special line $\ell$ and the line represented by $q_{1}$. For similar considerations that we made in the case of the $A_{3}$ singularity, the image of $W$ in the plane of the quintic $D$ is a line that intersects $D$ at two points, one with multiplicity four, the other with multiplicity one. Therefore this image can only be one of the three tangent lines of the singular point $p$.

The above suggest the following: the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times J C_{a} \times J C_{b} \rightarrow 0 \tag{4.1.36}
\end{equation*}
$$

with extension data

$$
\begin{align*}
& g_{1} \mapsto\left(\mathcal{O}_{T}\left(t_{3}-t_{2}\right), \mathcal{O}_{C_{a}}\left(q_{3}^{a}-q_{2}^{a}\right), \mathcal{O}_{C_{b}}\left(q_{3}^{b}-q_{2}^{b}\right)\right)  \tag{4.1.37}\\
& g_{2} \mapsto\left(\mathcal{O}_{T}\left(t_{3}-t_{1}\right), \mathcal{O}_{C_{a}}\left(q_{3}^{a}-q_{1}^{a}\right), \mathcal{O}_{C_{b}}\left(q_{3}^{b}-q_{1}^{b}\right)\right), \tag{4.1.38}
\end{align*}
$$

where $T, C_{a}, C_{b}$ are elliptic, $C_{a}, C_{b}$ are the two components of $C$ and $q_{i}^{a}, q_{i}^{b}$ are the marked points of $C_{a}$ and $C_{b}$.

Remark 4.1.39. According to Allcock (see e.g., [CMJL12, Thm. 2.1]), $X$ with a unique singularity, which is $D_{4}$ is strictly semi-stable, and $X$ degenerates (in the sense of [CMJL12, §2.1]) to a cubic threefold with three $D_{4}$ singularities. In particular, we should get the same type of data in the two
cases for $I J(X)$, which in fact we do, as we will see later.

### 4.1.11 $2 A_{1}$ cubic threefolds

If $X$ has two nodes, $D$ also has two nodes, say $p$ and $q$. The double cover $\widetilde{D}$ is then irreducible with four nodes $p^{+}, p^{-}, q^{+}, q^{-}$, with $p^{ \pm}$lying above $p$ and $q^{ \pm}$lying above $q$. The dual graph $\widetilde{\Gamma}$ of $\widetilde{D} \rightarrow D$ is

For the cohomology we have

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e^{+}, e^{-}, f^{+}, f^{-}\right\rangle  \tag{4.1.41}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e^{+}+e^{-}, f^{+}+f^{-}\right\rangle  \tag{4.1.42}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e^{+}-e^{-}, f^{+}-f^{-}\right\rangle  \tag{4.1.43}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e^{+}-e^{-}\right), \frac{1}{2}\left(f^{+}-f^{-}\right)\right\rangle . \tag{4.1.44}
\end{align*}
$$

Obviously $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. Therefore the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.45}
\end{equation*}
$$

with extension data

$$
\begin{align*}
& g_{1} \mapsto \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)  \tag{4.1.46}\\
& g_{2} \mapsto \mathcal{O}_{N \widetilde{D}}\left(q_{2}^{+}-q_{1}^{+}-q_{2}^{-}+q_{1}^{-}\right), \tag{4.1.47}
\end{align*}
$$

where $p_{1}^{+}$and $p_{2}^{+}$are obtained by desingularizing the node $p^{+}$, and similarly for the other points.
The normalization $N D$ is a genus four, trigonal curve. To see that it is non-hyperelliptic, we consider the conics of the plane of $D$ that go through the points $p$ and $q$. Since five points determine
a conic and two are now fixed, we can move three points freely on the plane. This gives us $6-3=3$ degrees of freedom. The intersection multiplicity of the conic in general is two at each the nodes, therefore there are six intersection points on $D$ other than the nodes. This gives us a base point free three dimensional family of degree six effective divisors (a $g_{6}^{3}$ ) on $N D$, and thus an embedding of $N D$ into $\mathbb{P}^{3}$ as a degree six curve. Therefore it cannot be hyperelliptic (for an alternative proof use [ACGH85, p. 13]) and the Prym of $N D$ is the Jacobian of $N C$. This also means that $N C$ has to be genus three and connected.

The curve $C$ has one singularity, a node at say $\xi$. The point $\xi$ represents the line $l^{\prime}$ of $X$ that connects the two singular points. The lines $\ell$ and $l^{\prime}$ span a three-space whose image along the projection from $\ell$ is the line that connects the points $p$ and $q$ of $D$. Now let's assume that $C$ was obtained from the projection from the node that corresponds to $p \in D$. Consider the $g_{3}^{1}$ of $N D$ that we get if we intersect $D$ with lines going through $p$. Then the line connecting $p$ and $q$ gives the divisor $q_{1}+q_{2}+r$ of the $g_{3}^{1}$, where $q_{1}, q_{2}$ are obtained from desingularizing $q$, and $r$ is the fifth intersection point between $D$ and the line connecting $p$ and $q$. Thus the extension data $\left(q_{2}^{+}-q_{1}^{+}-q_{2}^{-}+q_{1}^{-}\right)$above can be given as the difference of two points of $N C$, namely

$$
\begin{equation*}
q_{2}^{+}-q_{1}^{+}-q_{2}^{-}+q_{1}^{-}=\left(q_{1}^{-}+q_{2}^{+}+\tilde{r}\right)-\left(q_{1}^{+}+q_{2}^{-}+\tilde{r}\right)=\xi_{1}-\xi_{2} \in J(N C), \tag{4.1.48}
\end{equation*}
$$

where $\tilde{r} \in N \widetilde{D}$ is one of the points above $r \in N D$. Since the point $\xi \in C$ is mapped to the line connecting $p$ and $q$, this suggests that $\xi_{1}$ and $\xi_{2}$ come from the desingularization of $\xi$. We can of course do the projection of $X$ from the other node, the one that correspondes to $q$ and take the $g_{3}^{1}$ using lines going through $q$ and we get a similar result for the other extension data. Thus we have for the intermediate Jacobian:

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J(N C) \rightarrow 0 \tag{4.1.49}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto \mathcal{O}_{N C}\left(\eta_{1}-\eta_{2}\right)  \tag{4.1.50}\\
g_{2} & \mapsto \mathcal{O}_{N C}\left(\xi_{1}-\xi_{2}\right) \tag{4.1.51}
\end{align*}
$$

where $\eta_{i}$ and $\xi_{i}$ come from the desingularization of the node of $C$ when we use one of the nodes of $X$ as projection point, then the other one. When we use different nodes of $X$ for the projection to get $C$, we get different curves $C$, but their normalization $N C$ does not depend on the point of projection, and that is why we can talk about the points $\eta_{i}$ and $\xi_{i}$ on $N C$.

### 4.1.12 $\quad A_{1}+A_{2}$ cubic threefolds

Let's denote the $A_{1}$ singularity of $D$ by $p$ and the $A_{2}$ singularity by $q$. Then $\widetilde{D}$ has the singularities $p^{+}, p^{-}, q^{+}, q^{-}$. The stable reduction gives the curve $F$ with components $N D$ and an elliptic tail $T$, which are attached at the node $q=t, q \in N D, t \in T$. The curve $\widetilde{F}$ has components $N \widetilde{D}, T^{+}, T^{-}$ and nodes $p^{+}, p^{-}, q^{+}=t^{+}, q^{-}=t^{-}$. The dual graph of $\widetilde{F} \rightarrow F$ is

The cohomology is given by

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e^{+}, e^{-}\right\rangle  \tag{4.1.53}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e^{+}+e^{-}\right\rangle  \tag{4.1.54}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e^{+}-e^{-}\right\rangle  \tag{4.1.55}\\
\left.H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-}\right] & =\mathbb{Z}\left\langle\frac{1}{2}\left(e^{+}-e^{-}\right)\right\rangle . \tag{4.1.56}
\end{align*}
$$

Obviously $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. Therefore the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.57}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)\right) . \tag{4.1.58}
\end{equation*}
$$

The curve $N D$ is genus four and trigonal. It is non-hyperelliptic for the same reason given in the $2 A_{1}$ case. Therefore its Prym is the Jacobian of $N C$, which is necessarily genus three. If we consider the projection from the $A_{2}$ singularity of $X$ and the $g_{3}^{1}$ received from lines going through $q \in D$, for reasons explained in previous cases (e.g. $2 A_{1}$ ) the extension data is $\xi_{2}-\xi_{1}$, where the $\xi_{i}$ come from the desingularization of the $A_{1}$ singularity of $X$. Thus for the intermediate Jacobian we have

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0 \tag{4.1.59}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right) . \tag{4.1.60}
\end{equation*}
$$

### 4.1.13 $A_{1}+A_{3}$ cubic threefolds with irreducible discriminants

Let the $A_{1}$ singularity of $D$ be the point $p$, and the $A_{3}$ singularity of $D$ the point $q$. Then $\widetilde{D}$ has the singularities $p^{+}, p^{-}, q^{+}, q^{-}$. To get the stable reduction $F$, we desingularize $q$ and attach an elliptic tail $T$ to the points $q_{1}$ and $q_{2}$. These points come from the desingularization of $q$ and are attached to $t_{1}$ and $t_{2}$ of $T$. In $\widetilde{F}$, the stable reduction of $\widetilde{D}$, we then have the tails $T^{+}$and $T^{-}$and
the points $q_{i}^{ \pm}, t_{i}^{ \pm}$. The dual graph $\widetilde{\Gamma}$ then looks like

The cohomology is given by

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e^{+}, e^{-}, f_{2}^{+}-f_{1}^{+}, f_{2}^{-}-f_{1}^{-}\right\rangle  \tag{4.1.62}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e^{+}+e^{-}, f_{2}^{+}-f_{1}^{+}+f_{2}^{-}-f_{1}^{-}\right\rangle  \tag{4.1.63}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e^{+}-e^{-}, f_{2}^{+}-f_{1}^{+}-f_{2}^{-}+f_{1}^{-}\right\rangle  \tag{4.1.64}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e^{+}-e^{-}\right), \frac{1}{2}\left(f_{2}^{+}-f_{1}^{+}-f_{2}^{-}+f_{1}^{-}\right)\right\rangle . \tag{4.1.65}
\end{align*}
$$

Again we have $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. Therefore the intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.66}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)\right)  \tag{4.1.67}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}\left(t_{2}-t_{1}\right), \mathcal{O}_{N \widetilde{D}}\left(q_{2}^{+}-q_{1}^{+}-q_{2}^{-}+q_{1}^{-}\right)\right), \tag{4.1.68}
\end{align*}
$$

where $p_{i}^{ \pm}$come from the blow-ups of $p^{ \pm}$. The curve $N D$ is genus three, trigonal and nonhyperelliptic for the usual reason, therefore the Prym is the Jacobian of $N C$, where $N C$ is connected, genus two and hyperelliptic. Thus for the intermediate Jacobian we have

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0 \tag{4.1.69}
\end{equation*}
$$

For the usual reason the extension data is given by

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.70}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}\left(t_{2}-t_{1}\right), \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right), \tag{4.1.71}
\end{align*}
$$

where the $\xi_{i}$ and the $\eta_{i}$ come from the desingularization of the singularities of the $(2,3)$-curve $C$, the $\xi_{i}$ belonging to the original $A_{1}$ singularity and the $\eta_{i}$ belonging to the original $A_{3}$ singularity of $X$.

### 4.1.14 $A_{1}+A_{4}$ cubic threefolds with irreducible discriminants

This is very similar to the $A_{1}+A_{2}$ case. The only difference is that the tail $T$ is hyperelliptic genus two and $N D$ is genus three. The intermediate Jacobian is

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.72}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)\right), \tag{4.1.73}
\end{equation*}
$$

where the $p_{i}^{ \pm}$come from the desingularization of the nodes of $\widetilde{D}$ above the $A_{1}$ singularity of $D$. The normalization $N C$ of the (2,3)-curve is connected and genus two. The intermediate Jacobian using $N C$ is

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0 \tag{4.1.74}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right), \tag{4.1.75}
\end{equation*}
$$

where the $\xi_{i}$ come from the blow-up of the node of $C$ if the $A_{4}$ singularity of $X$ was used as center of projection to create $C$.

### 4.1.15 $A_{1}+A_{5}$ cubic threefolds with irreducible discriminants

This is similar to the $A_{1}+A_{3}$ case. The point $q \in D$ is now an $A_{5}$ singularity, the tail $T$ is now a hyperelliptic, genus two curve. The dual graph and the cohomology groups are the same, therefore the intermediate Jacobian is given as

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times P_{N \tilde{D} / N D} \rightarrow 0 \tag{4.1.76}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N \widetilde{D}}\left(p_{2}^{+}-p_{1}^{+}-p_{2}^{-}+p_{1}^{-}\right)\right)  \tag{4.1.77}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}\left(t_{2}-t_{1}\right), \mathcal{O}_{N \widetilde{D}}\left(q_{2}^{+}-q_{1}^{+}-q_{2}^{-}+q_{1}^{-}\right)\right) \tag{4.1.78}
\end{align*}
$$

The normalization $N D$ is hyperelliptic and genus two, therefore we cannot use the trigonal construction. By the hyperelliptic construction the Prym of the double cover is the Jacobian of some elliptic curve $G$, therefore we have

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times J G \rightarrow 0 \tag{4.1.79}
\end{equation*}
$$

Suspicion: $C$ is an irreducible (2,3)-curve with an $A_{5}$ singularity (or an $A_{1}$ and an $A_{3}$ singularity), thus NC is an elliptic curve and $G=N C$ via the hyperelliptic construction. The extension data is

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.80}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}\left(t_{2}-t_{1}\right), \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right), \tag{4.1.81}
\end{align*}
$$

where the $\xi_{i}$ come from the desingularization of the node and the $\eta_{i}$ come from the desingularization of the $A_{5}$ singular point.

### 4.1.16 $A_{1}+A_{7}$ cubic threefolds with irreducible discriminants

This is similar to the $A_{1}+A_{3}$ and the $A_{1}+A_{5}$ cases. Remark 4.1.24 also applies here. The dual graph and the cohomology groups are the same. The difference is that the tail $T$ is now hyperelliptic and genus three, while $N D$ is elliptic and thus its Prym variety is trivial. Therefore the intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \rightarrow 0 \tag{4.1.82}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto \mathcal{O}_{T}  \tag{4.1.83}\\
g_{2} & \mapsto \mathcal{O}_{T}\left(t_{2}-t_{1}\right) . \tag{4.1.84}
\end{align*}
$$

### 4.1.17 $2 A_{2}$ cubic threefolds with irreducible discriminants

In the stable reduction we have the elliptic tails $T_{1}, T_{2}$, and $T_{1}^{ \pm}, T_{2}^{ \pm}$. The dual graph $\widetilde{\Gamma}$ :

The cohomology groups are trivial and the intermediate Jacobian is compact. The normalization $N D$ is a trigonal, non-hyperelliptic, genus four curve. It is non-hyperelliptic for the usual reasons, see e.g. the $2 A_{1}$ case. The Prym of $N D$ is the Jacobian of the normalization $N C$ of the (2,3)-curve $C$. The curve $N C$ is genus three. Thus for the intermediate Jacobian we have:

$$
\begin{equation*}
I J(X)=J T_{1} \times J T_{2} \times J(N C) . \tag{4.1.86}
\end{equation*}
$$

### 4.1.18 $A_{2}+A_{3}$ cubic threefolds with irreducible discriminants

Let $p$ denote the $A_{2}$ singularity, and $q$ denote the $A_{3}$ singularity of $D$. In the stable reduction $T_{1}$ denotes the elliptic tail belonging to $p$, and $T_{2}$ denotes the hyperelliptic genus two tail belonging to $q$. In $F$ the tail $T_{2}$ is connected to $N D$ at the nodes $q_{a}=t_{2 a}$ and $q_{b}=t_{2 b}$. We have the tails $T_{1}^{ \pm}$ and $T_{2}^{ \pm}$as usual and the nodes $q_{a}^{ \pm}, q_{b}^{ \pm}, t_{2 a}^{ \pm}, t_{2 b}^{ \pm}$. The dual graph $\widetilde{\Gamma}$ :

The cohomology is then given by

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle e_{2 a}^{+}-e_{2 b}^{+}, e_{2 a}^{-}-e_{2 b}^{-}\right\rangle  \tag{4.1.88}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle e_{2 a}^{+}-e_{2 b}^{+}+e_{2 a}^{-}-e_{2 b}^{-}\right\rangle  \tag{4.1.89}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle e_{2 a}^{+}-e_{2 b}^{+}-e_{2 a}^{-}+e_{2 b}^{-}\right\rangle  \tag{4.1.90}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(e_{2 a}^{+}-e_{2 b}^{+}-e_{2 a}^{-}+e_{2 b}^{-}\right)\right\rangle . \tag{4.1.91}
\end{align*}
$$

Clearly $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$. The curve $N D$ is trigonal and genus three. It is also nonhyperelliptic for the usual reason. Its Prym is therefore the Jacobian of $N C$, which is a genus two curve. If $\xi_{1}, \xi_{2} \in N C$ are obtained by desingularizing the point of $C$ representing the $A_{3}$ singularity of $X$, the intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J(N C) \rightarrow 0 \tag{4.1.92}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2 b}-t_{2 a}\right), \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right) . \tag{4.1.93}
\end{equation*}
$$

### 4.1.19 $A_{2}+A_{4}$ cubic threefolds with irreducible discriminants

Similar to the $2 A_{2}$ case. The intermediate Jacobian is

$$
\begin{equation*}
I J(X)=J T_{1} \times J T_{2} \times J(N C), \tag{4.1.94}
\end{equation*}
$$

where $T_{1}$ is elliptic, $T_{2}$ is hyperelliptic, genus two and $N C$ is genus two.

### 4.1.20 $A_{2}+A_{5}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J G \rightarrow 0 \tag{4.1.95}
\end{equation*}
$$

where $T_{1}$ is elliptic, $T_{2}$ is hyperelliptic genus two and $G$ is elliptic.
Suspicion: NC is connected and elliptic and $G=N C$. The extension data is given by

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2}-t_{1}\right), \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right), \tag{4.1.96}
\end{equation*}
$$

where the points $\xi_{1}, \xi_{2} \in N C$ come from the desingularization of the singular point that represents the $A_{5}$ singularity of $X$.

### 4.1.21 $A_{2}+A_{7}$ cubic threefolds with irreducible discriminants

Remark 4.1.24 also applies here. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \rightarrow 0 \tag{4.1.97}
\end{equation*}
$$

where $T_{1}$ is elliptic and $T_{2}$ is hyperelliptic genus three. The extension data is given by

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2}-t_{1}\right)\right) . \tag{4.1.98}
\end{equation*}
$$

### 4.1.22 $2 A_{3}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J G \rightarrow 0 \tag{4.1.99}
\end{equation*}
$$

where $T_{1}, T_{2}, G$ are elliptic.
Suspicion: NC is connected and elliptic and $G=N C$. The extension data is given by

$$
\begin{align*}
& g_{1} \mapsto\left(\mathcal{O}_{T_{1}}\left(t_{1 b}-t_{1 a}\right), \mathcal{O}_{T_{2}}, \mathcal{O}_{N C}\left(\xi_{1 b}-\xi_{1 a}\right)\right)  \tag{4.1.100}\\
& g_{2} \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2 b}-t_{2 a}\right), \mathcal{O}_{N C}\left(\xi_{2 b}-\xi_{2 a}\right)\right), \tag{4.1.101}
\end{align*}
$$

where the points $\xi_{1 a}, \xi_{1 b}, \xi_{2 a}, \xi_{2 b} \in N C$ come from the desingularization of the singular points that represent the $A_{3}$ singularities of $X$.

### 4.1.23 $A_{3}+A_{4}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J G \rightarrow 0 \tag{4.1.102}
\end{equation*}
$$

where $T_{1}, G$ are elliptic and $T_{2}$ is hyperelliptic genus two.
Suspicion: NC is connected and elliptic and $G=N C$. The extension data is given by

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}\left(t_{2}-t_{1}\right), \mathcal{O}_{T_{2}}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right), \tag{4.1.103}
\end{equation*}
$$

where the points $\xi_{1}, \xi_{2}, \in N C$ come from the desingularization of the singular point that represents the $A_{3}$ singularity of $X$.

### 4.1.24 $A_{3}+A_{5}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \rightarrow 0, \tag{4.1.104}
\end{equation*}
$$

where $T_{1}$ is elliptic and $T_{2}$ is hyperelliptic, genus two. The extension data is given by

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T_{1}}\left(t_{1 b}-t_{1 a}\right), \mathcal{O}_{T_{2}}\right)  \tag{4.1.105}\\
g_{2} & \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2 b}-t_{2 a}\right)\right) . \tag{4.1.106}
\end{align*}
$$

### 4.1.25 $2 A_{4}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is

$$
\begin{equation*}
I J(X)=J T_{1} \times J T_{2} \times J G, \tag{4.1.107}
\end{equation*}
$$

where $T_{1}, T_{2}$ are hyperelliptic, genus two and $G$ is elliptic.
Suspicion: NC is connected and elliptic and $G=N C$.

### 4.1.26 $A_{4}+A_{5}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \rightarrow 0 \tag{4.1.108}
\end{equation*}
$$

where $T_{1}, T_{2}$ are hyperelliptic, genus two. The extension data is given by

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2}-t_{1}\right)\right) . \tag{4.1.109}
\end{equation*}
$$

### 4.1.27 $3 A_{1}$ cubic threefolds with irreducible discriminants

Similar to the $2 A_{1}$ case. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{3} \rightarrow I J(X) \rightarrow J(N C) \rightarrow 0, \tag{4.1.110}
\end{equation*}
$$

with extension data

$$
\begin{align*}
& g_{1} \mapsto \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)  \tag{4.1.111}\\
& g_{2} \mapsto \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)  \tag{4.1.112}\\
& g_{3} \mapsto \mathcal{O}_{N C}\left(\mu_{2}-\mu_{1}\right), \tag{4.1.113}
\end{align*}
$$

where $N C$ is connected, hyperellitpic and genus two and the points $\xi_{i}, \eta_{i}, \mu_{i} \in N C$ come from the desingularization of nodes of $C$ corresponding to the nodes of $X$.

### 4.1.28 $2 A_{1}+A_{2}$ cubic threefolds with irreducible discriminants

Similar to the $A_{1}+A_{2}$ case. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times J(N C) \rightarrow 0 \tag{4.1.114}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.115}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right), \tag{4.1.116}
\end{align*}
$$

where $T$ is an elliptic tail, $N C$ is connected, hyperellitpic and genus two and the points $\xi_{i}, \eta_{i} \in N C$ come from the desingularization of nodes of $C$ corresponding to the nodes of $X$.

### 4.1.29 $2 A_{1}+A_{3}$ cubic threefolds with irreducible discriminants

Similar to the $A_{1}+A_{3}$ case. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{3} \rightarrow I J(X) \rightarrow J T \times J G \rightarrow 0 \tag{4.1.117}
\end{equation*}
$$

where $T$ is an elliptic tail and $G$ is also elliptic.
Suspicion: NC is connected and elliptic and $G=N C$. The extension data is given by

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.118}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right)  \tag{4.1.119}\\
g_{3} & \mapsto\left(\mathcal{O}_{T}\left(t_{2}-t_{1}\right), \mathcal{O}_{N C}\left(\mu_{2}-\mu_{1}\right)\right), \tag{4.1.120}
\end{align*}
$$

where the points $\xi_{i}, \eta_{i} \in N C$ come from the desingularization of nodes of $C$ corresponding to the $A_{1}$ singularities of $X$, and the points $\mu_{i}$ are desingularization of the singularity corresponding to the $A_{3}$ point of $X$.

### 4.1.30 $2 A_{1}+A_{4}$ cubic threefolds with irreducible discriminants

Similar to the $2 A_{1}+A_{2}$ case. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T \times J G \rightarrow 0 \tag{4.1.121}
\end{equation*}
$$

where $T$ is a hyperelliptic, genus two tail and $G$ is elliptic.
Suspicion: NC is connected and elliptic and $G=N C$. The extension data is given by

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.122}\\
g_{2} & \mapsto\left(\mathcal{O}_{T}, \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right), \tag{4.1.123}
\end{align*}
$$

where the points $\xi_{i}, \eta_{i} \in N C$ come from the desingularization of nodes of $C$ corresponding to the node of $X$.

### 4.1.31 $2 A_{1}+A_{5}$ cubic threefolds with irreducible discriminants

Similar to the $2 A_{1}+A_{3}$ case. The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{3} \rightarrow I J(X) \rightarrow J T \rightarrow 0 \tag{4.1.124}
\end{equation*}
$$

with extension data

$$
\begin{align*}
g_{1} & \mapsto \mathcal{O}_{T}  \tag{4.1.125}\\
g_{2} & \mapsto \mathcal{O}_{T}  \tag{4.1.126}\\
g_{3} & \mapsto \mathcal{O}_{T}\left(t_{2}-t_{1}\right), \tag{4.1.127}
\end{align*}
$$

where $T$ is a hyperelliptic, genus two tail.

### 4.1.32 $A_{1}+2 A_{2}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J(N C) \rightarrow 0 \tag{4.1.128}
\end{equation*}
$$

with extension data

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right), \tag{4.1.129}
\end{equation*}
$$

where $T_{1}, T_{2}$ are elliptic tails, $N C$ is connected, genus two, hyperelliptic.

### 4.1.33 $A_{1}+A_{2}+A_{3}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J G \rightarrow 0 \tag{4.1.130}
\end{equation*}
$$

where $T_{1}, T_{2}$ are elliptic tails and $G$ is also elliptic.

Suspicion: NC is connected, elliptic and $G=N C$. The extension data is

$$
\begin{align*}
g_{1} & \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right)  \tag{4.1.131}\\
g_{2} & \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2}-t_{1}\right), \mathcal{O}_{N C}\left(\eta_{2}-\eta_{1}\right)\right), \tag{4.1.132}
\end{align*}
$$

where the $\xi_{i}$ belong to the $A_{1}$ singularity and the $\eta_{i}$ belong to the $A_{3}$ singularity of $X$.

### 4.1.34 $A_{1}+A_{2}+A_{4}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow \mathbb{C}^{*} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \times J G \rightarrow 0 \tag{4.1.133}
\end{equation*}
$$

where $T_{1}$ is an elliptic tail, $T_{2}$ is a hyperelliptic, genus two tail and $G$ is elliptic.
Suspicion: NC is connected, elliptic and $G=N C$. The extension data is

$$
\begin{equation*}
g \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}, \mathcal{O}_{N C}\left(\xi_{2}-\xi_{1}\right)\right), \tag{4.1.134}
\end{equation*}
$$

where the $\xi_{i}$ belong to the $A_{1}$ singularity of $X$.

### 4.1.35 $A_{1}+A_{2}+A_{5}$ cubic threefolds with irreducible discriminants

The intermediate Jacobian is given by

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow J T_{1} \times J T_{2} \rightarrow 0 \tag{4.1.135}
\end{equation*}
$$

with extension data

$$
\begin{align*}
& g_{1} \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\right)  \tag{4.1.136}\\
& g_{2} \mapsto\left(\mathcal{O}_{T_{1}}, \mathcal{O}_{T_{2}}\left(t_{2}-t_{1}\right)\right), \tag{4.1.137}
\end{align*}
$$

where $T_{1}$ is an elliptic tail and $T_{2}$ is a hyperelliptic, genus two tail.

### 4.2 Quintic $=2$ Conics +1 Line

### 4.2.1 $8 A_{1}$ cubic threefolds

Two conics and a line in the plane in general position have eight nodal intersections. Since there is no need for a stable reduction, and $N D$ and $N \widetilde{D}$ are disjoint unions of genus zero curves, the intermediate Jacobian has no compact part, therefore

$$
\begin{equation*}
I J(X) \cong\left(\mathbb{C}^{*}\right)^{5} \tag{4.2.1}
\end{equation*}
$$

### 4.3 Quintic $=$ Conic +3 Lines

### 4.3.1 $9 A_{1}$ cubic threefolds

A conic and three lines in the plane in general position have nine nodal intersections. Since there is no need for a stable reduction, and $N D$ and $N \widetilde{D}$ are disjoint unions of genus zero curves, the intermediate Jacobian has no compact part, therefore

$$
\begin{equation*}
I J(X) \cong\left(\mathbb{C}^{*}\right)^{5} \tag{4.3.1}
\end{equation*}
$$

### 4.3.2 $3 D_{4}$ cubic threefolds

There is a unique cubic threefold $X$ with three $D_{4}$ singularities with equation

$$
\begin{equation*}
x_{0} x_{1} x_{2}+x_{3}^{3}+x_{4}^{3}=0, \tag{4.3.2}
\end{equation*}
$$

in the sense that any other cubic threefold with three $D_{4}$ singularities can be obtained under projective transformation of this equation. The three singularities occur at the points $p_{1}=(1: 0$ : $0: 0: 0), p_{2}=(0: 1: 0: 0: 0), p_{3}=(0: 0: 1: 0: 0)$. Since permuting the coordinates $x_{0}, x_{1}, x_{2}$ does not change the equation of $X$, we can see that $X$ is symmetric with respect to the three singularities. The equation of $X$ also tells us about the $(2,3)$-curve $C$, namely it is the intersection of the quadric $\left\{x_{1} x_{2}=0\right\}$ and the cubic $\left\{x_{3}^{3}+x_{4}^{3}=0\right\}$ in $\mathbb{P}^{3}$. The former is the union of the planes
$\left\{x_{1}=0\right\}$ and $\left\{x_{2}=0\right\}$, while the latter is the union of three planes intersecting one another in the common line $\left\{x_{3}=x_{4}=0\right\}$. Therefore $C$ consists of two sets of three lines, each set of three lines being on the same plane and intersecting in a common point giving a $D_{4}$ singularity. Lines from different sets meet each other in three pairs, giving three $A_{1}$ singularities on the intersection of the planes $\left\{x_{1}=0\right\}$ and $\left\{x_{2}=0\right\}$. The three $A_{1}$ singularities come from the blow-up of $X$ at $p_{1}$, while the two $D_{4}$ singularities (located at $(1: 0: 0: 0)$ and $\left.(0: 1: 0: 0)\right)$ come from $p_{2}$ and $p_{3}$. Since $C$ consists of six lines, there are six planes contained in $X$ and containing $p_{1}$. Three of them contains the line through $p_{1}$ and $p_{2}$ and the other three contains the line through $p_{1}$ and $p_{3}$. Because of symmetry the same statement about the six planes is true for $p_{2}$ and $p_{3}$, therefore for any two singular points there are three planes in $X$ containing the two singular points.

The plane quintic discriminant curve $D$ has three $D_{4}$ singularities which we also denote by $p_{1}, p_{2}, p_{3}$. They are formed the following way: the three lines $L_{12}, L_{13}, L_{23}$ of the quintic intersect each other in the points $p_{1}, p_{2}, p_{3}$, and the conic $Q$ goes through these intersections. Thus $D$ consists of four irreducible components, each non-singular and genus zero.

By Hurwitz's theorem a connected double cover of a genus zero curve must have ramification points, therefore in $\widetilde{D}$ there must be two identical copies above each component of $D$. Therefore $\widetilde{D}$ consists of eight genus zero curves labelled $L_{i j}^{ \pm}, Q^{ \pm}$, connected through six $D_{4}$ singularities $p_{i}^{ \pm}$. These eight curves must be connected in a way that the resulting $\widetilde{D}$ is connected. We want to figure out the configuration of these connections.

Let $p_{i}^{+}$be three points on $Q^{+}$and $p_{i}^{-}$be three points on $Q^{-}$. These are isomorphic copies of $Q$ with the three points $p_{i}$. The curves $Q^{+}$and $Q^{-}$are obviously disjoint, because the double cover
of $Q$ is their disjoint union. We want to find how the six curves $L_{i j}^{ \pm}$are connected to the curves $Q^{ \pm}$. The curve $L_{i j}^{+}$must connect to one of $p_{i}^{+}, p_{i}^{-}$and also one of $p_{j}^{+}, p_{j}^{-}$. Then $L_{i j}^{-}$will connect to the other points of each of these pairs.

Let's consider the straight line $L_{12}$ of $D$. This represents a three-space $W_{12}$ in $\mathbb{P}^{4}$. We want to describe the cubic surface $X \cap W_{12}$. The three-space $W_{12}$ can be obtained as the span of the non-special line $\ell$ and the line through $p_{1}$ and $p_{2}$ of $X$. Since the entire line $L_{12}$ is part of the discriminant $D$, any plane of $W_{12}$ conaining $\ell$ intersects $X$ in three distinct lines. This means that the cubic surface $X \cap W_{12}$ has infinitely many straight lines. Thus the possibilities for $X \cap W_{12}$ is that it is either a reducible cubic surface, an irreducible cone, or an irreducible ruled surface (a scroll). It is easy to see that $X \cap W_{12}$ cannot be an irreducible cone, since all lines go through one point in an irreducible cone, while in $X \cap W_{12}$ the lines $\ell$ and the one through $p_{1}$ and $p_{2}$ are skew. To find out about $X \cap W_{12}$, we have to go back to the equation of $X$ and see the possible intersections that we get with three-spaces. The general equation of a three-space in $\mathbb{P}^{4}$ is

$$
\begin{equation*}
a x_{0}+b x_{1}+c x_{2}+d x_{3}+e x_{4}=0 \tag{4.3.3}
\end{equation*}
$$

Since the three-space belonging to $L_{12}$ contains $p_{1}$ and $p_{2}$, but not $p_{3}$, we have $a=b=0$ and $c \neq 0$. We can choose $c=-1$ and get $x_{2}=d x_{3}+e x_{4}$, where $d$ and $e$ are non-homogeneous coordinates now. In the case $d=e=0, W_{12}$ is given by $x_{2}=0$ and the equation of $X \cap W_{12}$ is just $x_{3}^{3}+x_{4}^{3}=0$, which is the union of three planes intersecting one another in a common line, the line through $p_{1}$ and $p_{2}$. This cannot be the case, because no matter how we would pick the non-special line $\ell \subset X$, the image of the entire line through $p_{1}$ and $p_{2}$ would be a point in the plane of the discriminant curve. Therefore $d=e=0$ cannot be, and because of symmetricity we can assume that $d \neq 0$. For $X \cap W_{12}$ we have

$$
\begin{equation*}
d x_{0} x_{1} x_{3}+e x_{0} x_{1} x_{4}+x_{3}^{3}+x_{4}^{3}=0 \tag{4.3.4}
\end{equation*}
$$

To find the singularities we consider the Jacobian

$$
\left[\begin{array}{lll}
x_{1}\left(d x_{3}+e x_{4}\right) & x_{0}\left(d x_{3}+e x_{4}\right) & d x_{0} x_{1}+3 x_{3}^{2} \tag{4.3.5}
\end{array} \quad e x_{0} x_{1}+3 x_{4}^{2}\right] .
$$

It is easy to see that if we assume that $d x_{3}+e x_{4} \neq 0$, we eventually have to conclude that $x_{0}=x_{1}=x_{3}=x_{4}=0$, which is not possible, so we assume that $d x_{3}+e x_{4}=0$. Since $d \neq 0$, we have $x_{3}=-\frac{e}{d} x_{4}$ and the equation of $X \cap W_{12}$ becomes

$$
\begin{equation*}
x_{0} x_{1}\left(d x_{3}+e x_{4}\right)-\frac{e^{3}}{d^{3}} x_{4}^{3}+x_{4}^{3}=\left(1-\frac{e^{3}}{d^{3}}\right) x_{4}^{3}=0 . \tag{4.3.6}
\end{equation*}
$$

Case I: $e^{3} \neq d^{3}$. Then necessarily $x_{4}=0$ and therefore $x_{3}=0$. From the third and fourth entries of the Jacobian we see that either $x_{0}$ or $x_{1}$ must be zero, therefore in this case the only singularities are at $(1: 0: 0: 0)$ and $(0: 1: 0: 0)$ and they come from $p_{1}$ and $p_{2}$. Since we only have isolated singularities, the cubic surface can only have finitely many lines, so this case cannot give the cubic surface we are looking for.

Case II: $e^{3}=d^{3}$. Under the assumption $d x_{3}+e x_{4}=0$ and $e^{3}=d^{3}$, it is easy to see that the third and fourth entries of the Jacobian give the same equation. The locus of the singularities is given by the equations

$$
\begin{array}{r}
d x_{3}+e x_{4}=0 \\
d x_{0} x_{1}+3 x_{3}^{2}=0 \tag{4.3.8}
\end{array}
$$

which is a plane quadric. Therefore $X \cap W_{12}$ cannot be an irreducible ruled cubic surface, because that has a double line singularity. Thus $X \cap W_{12}$ is reducible, and is the union of a plane and a quadric surface. Indeed, $\left(d x_{3}+e x_{4}\right)$ can be factored out from the equation (4.3.4) if $e^{3}=d^{3}$, and what remains is an irreducible quadric. The singular points $p_{1}$ and $p_{2}$ must be singular in $X \cap W_{12}$ as well, therefore they belong to both the plane and the quadric surface.

Remark: we see that case I is the more general case, so we might wonder if we could pick the non-special line $\ell$ as one of the lines that occur in $X \cap W_{12}$, when $W_{12}$ belongs to case I, i.e. when $e^{3} \neq d^{3}$. In fact it is not possible, because in case I $X \cap W_{12}$ has at best two $A_{2}$ singularities (a $D_{4}$ in a threefold of $\mathbb{P}^{4}$ becomes an $A_{2}$ when intersected with a general three-space), and we know from §3.1.6, that all lines in a cubic surface with two $A_{2}$ singularities pass through at least one of the singularities. Therefore we could not find a non-special line there.

We have shown above that if $W_{12}$ is the three-space belonging to $L_{12}$ of $D$, then $X \cap W_{12}$ is the union of a plane $\Pi_{12}$ and a quadric surface $R_{12}$, where the singularities $p_{1}$ and $p_{2}$ lie on the intersection $\Pi_{12} \cap R_{12}$ and $\Pi_{12}$ is one of the three planes of $X$ mentioned above containing these two singular points. As the non-special line cannot intersect the line through $p_{1}$ and $p_{2}$, it must lie on the quadric $R_{12}$.

Next we want to identify the curves $L_{12}^{+}, L_{12}^{-}$and see how they connect to the other curves $L_{i j}^{ \pm}$. If we pick a point of $L_{12}$, that corresponds to a plane $Y$ of $W_{12}$ containing $\ell$. Then $Y$ necessarily has two additional lines when intersected with $X$, one in the plane $\Pi_{12}$, the other in the quadric $R_{12}$. One of these lines represent a point of $L_{12}^{+}$, the other a point of $L_{12}^{-}$. Let's say that the lines on $\Pi_{12}$ correspond to the points of $L_{12}^{+}$, while the lines on $R_{12}$ correspond to the points of $L_{12}^{-}$, and similarly for the other $L_{i j}^{ \pm}$. The question is does $L_{12}^{+}$connect to $L_{13}^{+}$or to $L_{13}^{-}$? This connection occurs above the point $p_{1}$, so we have to consider the plane spanned by $\ell$ and $p_{1}$ and the two residual lines of intersection with $X$, say $l^{+}$and $l^{-}$, where $l^{+}$is the line on the plane $\Pi_{12}$ and $l^{-}$is the one on $R_{12}$. The question is does the line $l^{+}$lie on the plane $\Pi_{13}$ or on the quadric $R_{13}$ of the cubic surface $X \cap W_{13}$ belonging to $L_{13}$ ? The plane $\Pi_{13}$ of $X \cap W_{13}$ is one of the three planes in $X$ containing both $p_{1}$ and $p_{3}$. Two of these three planes intersect $\Pi_{12}$ in only a point (which is $p_{1}$ ), and only the third intersect it in a line (the curve $C$ explains why). This line corresponds to one of the $A_{1}$ singularities of the (2,3)-curve $C$ and it is one of the three distinguished lines in the tangent cone of the $D_{4}$ singular point $p_{1}$. If $\Pi_{12}$ and $\Pi_{13}$ intersect only in a point, $l^{+}$must lie on $R_{13}$, and thus $L_{12}^{+}$connects with $L_{13}^{-}$. Let's assume now that $\Pi_{13}$ is the plane that intersects $\Pi_{12}$ in a line. The question is therefore is it possible that $l^{+}$is the same as the intersection of $\Pi_{12}$ and $\Pi_{13}$ ? If it was, then the non-special line $\ell$ would intersect $\Pi_{12} \cap \Pi_{13}$, because $\ell$ and $l^{+}$intersect. But that is not possible, because $\Pi_{12} \cap \Pi_{13}$ represents the tangent direction at $p_{1} \in X$ that gives one of the $A_{1}$ singularities when $p_{1}$ is blown up, thus the span of $\ell$ and $\Pi_{12} \cap \Pi_{13}$ must be a three-space that projects to one of the tangent lines at $p_{1} \in D$ in the plane of the discriminant $D$. Thus $\ell$ cannot intersect $\Pi_{12} \cap \Pi_{13}$, and $l^{+}$does not lie in $\Pi_{13}$, but in $R_{13}$. Therefore $L_{12}^{+}$connects to $L_{13}^{-}$in this case, as well, and thus $L_{12}^{-}$must connect to $L_{13}^{+}$. Because of symmetricity, similar statements are true above the other singular points, as well. Therefore the $L_{i j}^{ \pm}$lines are connected to each other
in a single cycle of six elements (as opposed to two cycles of three, for example).
The next question is how do the curves $Q^{+}$and $Q^{-}$fit into this arrangement? As the configuration must be symmetric with respect to the singularities, the only possible way to do this (up to some relabelling) is if the lines $L_{i j}^{ \pm}$keep alternating between $Q^{+}$and $Q^{-}$, that is each $L_{i j}^{ \pm}$is connected to $Q^{+}$at one point and $Q^{-}$at the other.

Now that we have a clear understanding of the double cover $\widetilde{D} \rightarrow D$, we want to describe the stable reduction $\widetilde{F} \rightarrow F$. To resolve the $D_{4}$ singularities of $\widetilde{D}$ and $D$, we add an elliptic tail for each singularity. The three irreducible components that are connected at a singularity of $\widetilde{D}$ or $D$ will connect to three distinct points of the corresponding tail curve. We have the tails $T_{i}$ in $F$ for the singularities $p_{i}$ and the tails $T_{i}^{ \pm}$in $\widetilde{F}$ for the singularities $p_{i}^{ \pm}$. On each $T_{i}^{ \pm}$there are connection points where the other components connect through a node, these nodes are labelled as ${ }^{x} t_{i}^{ \pm}$, where $x$ can be one of $(q, 12,13,23)$ depending on what component is connected to $T_{i}^{ \pm}$at that node. To get the stable reduction of $\widetilde{D}$ it is not enough to blow up the singularities and add the tails described above. The problem is that the genus zero curves $L_{i j}^{ \pm}$have only two marked points, so their automorphism groups are infinite. This means that they have to be contracted to a point and the two tails that used to be connected to a curve $L_{i j}^{ \pm}$will now be connected to each other through a node that comes from the contraction of these curves. The components and the connections are described by the following table:

|  | $Q^{+}$ | $Q^{-}$ | $T_{1}^{+}$ | $T_{2}^{+}$ | $T_{3}^{+}$ | $T_{1}^{-}$ | $T_{2}^{-}$ | $T_{3}^{-}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $Q^{+}$ | - | - | ${ }^{q} t_{1}^{+}$ | ${ }^{q} t_{2}^{+}$ | ${ }^{q} t_{3}^{+}$ | - | - | - |
| $Q^{-}$ | - | - | - | - | - | ${ }^{q} t_{1}^{-}$ | ${ }^{q} t_{2}^{-}$ | ${ }^{q} t_{3}^{-}$ |
| $T_{1}^{+}$ | ${ }^{q} t_{1}^{+}$ | - | - | - | - | - | ${ }^{12} t_{1}^{+}={ }^{12} t_{2}^{-}$ | ${ }^{13} t_{1}^{+}={ }^{13} t_{3}^{-}$ |
| $T_{2}^{+}$ | ${ }^{q} t_{2}^{+}$ | - | - | - | - | ${ }^{12} t_{2}^{+}={ }^{12} t_{1}^{-}$ | - | ${ }^{23} t_{2}^{+}={ }^{23} t_{3}^{-}$ |
| $T_{3}^{+}$ | ${ }^{q} t_{3}^{+}$ | - | - | - | - | ${ }^{13} t_{3}^{+}={ }^{13} t_{1}^{-}$ | ${ }^{23} t_{3}^{+}={ }^{23} t_{2}^{-}$ | - |
| $T_{1}^{-}$ | - | ${ }^{q} t_{1}^{-}$ | - | ${ }^{12} t_{1}^{-}={ }^{12} t_{2}^{+}$ | ${ }^{13} t_{1}^{-}={ }^{13} t_{3}^{+}$ | - | - | - |
| $T_{2}^{-}$ | - | ${ }^{q} t_{2}^{-}$ | ${ }^{12} t_{2}^{-}={ }^{12} t_{1}^{+}$ | - | ${ }^{23} t_{2}^{-}={ }^{23} t_{3}^{+}$ | - | - | - |
| $T_{3}^{-}$ | - | ${ }^{q} t_{3}^{-}$ | ${ }^{13} t_{3}^{-}={ }^{13} t_{1}^{+}$ | ${ }^{23} t_{3}^{-}={ }^{23} t_{2}^{+}$ | - | - | - | - |

This gives the dual graph $\widetilde{\Gamma}$ :

With 8 vertices and 12 edges the Euler number of the graph is 4 , therefore $H_{1}(\widetilde{\Gamma}, \mathbb{Z})=\mathbb{Z}^{5}$. In fact
we have:

$$
\begin{gather*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z})=\mathbb{Z}\left\langle f_{1}^{+}-e_{2}^{-}+e_{3}^{-}+f_{3}^{-},\right. \\
f_{2}^{-}+f_{3}^{+}-e_{1}^{-}+e_{2}^{-}, \\
f_{1}^{-}+f_{2}^{+}-e_{3}^{-}+e_{1}^{-},  \tag{4.3.10}\\
e_{3}^{+}+f_{3}^{+}+f_{1}^{+}-e_{2}^{+}, \\
\left.-e_{1}^{+}+f_{3}^{-}+f_{2}^{+}+e_{2}^{+}\right\rangle \\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}=\mathbb{Z}\left\langle f_{1}^{+}-e_{2}^{-}+e_{3}^{-}+f_{3}^{-}+e_{3}^{+}+f_{3}^{+}+f_{1}^{+}-e_{2}^{+},\right. \\
f_{2}^{-}+f_{3}^{+}-e_{1}^{-}+e_{2}^{-}-e_{1}^{+}+f_{3}^{-}+f_{2}^{+}+e_{2}^{+},  \tag{4.3.11}\\
\left.f_{1}^{+}+f_{2}^{-}+f_{3}^{+}+f_{1}^{-}+f_{2}^{+}+f_{3}^{-}\right\rangle \\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-}=\mathbb{Z}\left\langle f_{1}^{+}-e_{2}^{-}+e_{3}^{-}+f_{3}^{-}-e_{3}^{+}-f_{3}^{+}-f_{1}^{+}+e_{2}^{+},\right.  \tag{4.3.12}\\
\\
\left.f_{2}^{-}+f_{3}^{+}-e_{1}^{-}+e_{2}^{-}+e_{1}^{+}-f_{3}^{-}-f_{2}^{+}-e_{2}^{+}\right\rangle,  \tag{4.3.13}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]}=\mathbb{Z}\left\langle\frac{1}{2}\left(f_{1}^{+}-e_{2}^{-}+e_{3}^{-}+f_{3}^{-}-e_{3}^{+}-f_{3}^{+}-f_{1}^{+}+e_{2}^{+}\right),\right. \\
\left.\frac{1}{2}\left(f_{2}^{-}+f_{3}^{+}-e_{1}^{-}+e_{2}^{-}+e_{1}^{+}-f_{3}^{-}-f_{2}^{+}-e_{2}^{+}\right)\right\rangle,
\end{gather*}
$$

or using the cycles indicated on the graph:

$$
\begin{align*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z}) & =\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowleft}, \mathbf{B}_{\circlearrowleft}, \mathbf{C}_{\circlearrowright}, \mathbf{D}_{\circlearrowleft}, \mathbf{E}_{\circlearrowleft}\right\rangle  \tag{4.3.14}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+} & =\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowleft}+\mathbf{D}_{\circlearrowleft}, \mathbf{B}_{\circlearrowleft}+\mathbf{E}_{\circlearrowleft}, \mathbf{A}_{\circlearrowleft}+\mathbf{B}_{\circlearrowright}+\mathbf{C}_{\circlearrowleft}\right\rangle  \tag{4.3.15}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-} & =\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowleft}-\mathbf{D}_{\circlearrowleft}, \mathbf{B}_{\circlearrowleft}-\mathbf{E}_{\circlearrowleft}\right\rangle  \tag{4.3.16}\\
H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{[-]} & =\mathbb{Z}\left\langle\frac{1}{2}\left(\mathbf{A}_{\circlearrowleft}-\mathbf{D}_{\circlearrowleft}\right), \frac{1}{2}\left(\mathbf{B}_{\circlearrowright}-\mathbf{E}_{\circlearrowleft}\right)\right\rangle . \tag{4.3.17}
\end{align*}
$$

The picture may become clearer if we introduce

$$
\begin{equation*}
\mathbf{F}_{\circlearrowright}:=\mathbf{A}_{\circlearrowright}+\mathbf{B}_{\circlearrowright}+\mathbf{C}_{\circlearrowright}=f_{1}^{+}+f_{2}^{-}+f_{3}^{+}+f_{1}^{-}+f_{2}^{+}+f_{3}^{-}, \tag{4.3.18}
\end{equation*}
$$

a cycle around the hexagone of the $T_{i}^{ \pm}$in a clockwise direction. Then choosing a new basis we have

$$
\begin{equation*}
H_{1}(\widetilde{\Gamma}, \mathbb{Z})=\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowright}, \mathbf{D}_{\circlearrowleft}, \mathbf{B}_{\circlearrowright}, \mathbf{E}_{\circlearrowleft}, \mathbf{F}_{\circlearrowright}\right\rangle, \tag{4.3.19}
\end{equation*}
$$

and using this basis the matrix of $\iota$ is

$$
\left[\begin{array}{lllll}
0 & 1 & 0 & 0 & 0  \tag{4.3.20}\\
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1
\end{array}\right],
$$

and we have

$$
\begin{align*}
& H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}=\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowright}+\mathbf{D}_{\circlearrowleft}, \mathbf{B}_{\circlearrowright}+\mathbf{E}_{\circlearrowleft}, \mathbf{F}_{\circlearrowright}\right\rangle  \tag{4.3.21}\\
& H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{-}=\mathbb{Z}\left\langle\mathbf{A}_{\circlearrowright}-\mathbf{D}_{\circlearrowleft}, \mathbf{B}_{\circlearrowright}-\mathbf{E}_{\circlearrowleft}\right\rangle . \tag{4.3.22}
\end{align*}
$$

It is not true that $(1+\iota) H_{1}(\widetilde{\Gamma}, \mathbb{Z})=H_{1}(\widetilde{\Gamma}, \mathbb{Z})^{+}$, because $\iota\left(\mathbf{F}_{\circlearrowright}\right)=\mathbf{F}_{\circlearrowright}$ for the basis element $\mathbf{F}_{\circlearrowright}$. Therefore $k=1$ in (3.3.7), and $G=(\mathbb{Z} / 2 \mathbb{Z})^{d}$, where $d$ is either 0 or 1 . Thus the intermediate Jacobian is given by the sequence

$$
\begin{equation*}
1 \rightarrow\left(\mathbb{C}^{*}\right)^{2} \rightarrow I J(X) \rightarrow\left(J T_{1} \times J T_{2} \times J T_{3}\right) / G \rightarrow 0 \tag{4.3.23}
\end{equation*}
$$

The extension data is given by

$$
\begin{align*}
& g_{1} \mapsto\left[\mathcal{O}_{T_{1}}\left({ }^{13} t_{1}-{ }^{12} t_{1}\right), \mathcal{O}_{T_{2}}\left({ }^{q} t_{2}-{ }^{12} t_{2}\right), \mathcal{O}_{T_{3}}\left({ }^{13} t_{3}-{ }^{q} t_{3}\right)\right]  \tag{4.3.24}\\
& g_{2} \mapsto\left[\mathcal{O}_{T_{1}}\left({ }^{q} t_{1}-{ }^{13} t_{1}\right), \mathcal{O}_{T_{2}}\left({ }^{23} t_{2}-{ }^{q} t_{2}\right), \mathcal{O}_{T_{3}}\left({ }^{23} t_{3}-{ }^{13} t_{3}\right)\right], \tag{4.3.25}
\end{align*}
$$

where ${ }^{j k} t_{i}$ is the node of $T_{i}$ and $L_{j k}$ on $T_{i}$ and ${ }^{q} t_{i}$ is the node of $T_{i}$ and $Q$ on $T_{i}$.

### 4.4 Quintic $=5$ Lines

### 4.4.1 $10 A_{1}$ cubic threefolds

For reference, see [Gw05]. The cubic threefold $X$ with ten nodes is the Segre Cubic, and it is unique up to projective transformation. It can be given in $\mathbb{P}^{5}$ as the intersection of the cubic

$$
\begin{equation*}
\sum_{i=0}^{5} x_{i}^{3}=0 \tag{4.4.1}
\end{equation*}
$$

and the hypersurface

$$
\begin{equation*}
\sum_{i=0}^{5} x_{i}=0 \tag{4.4.2}
\end{equation*}
$$

In $\mathbb{P}^{4}$ it is defined by the equation

$$
\begin{equation*}
\sum_{\substack{i<j<k \\ i, j, k \in\{0, \ldots, 4\}}} 2 x_{i} x_{j} x_{k}+\sum_{\substack{i \neq j \\ i, j \in\{0, \ldots, 4\}}} x_{i}^{2} x_{j}=0 \tag{4.4.3}
\end{equation*}
$$

$X$ contains 15 planes, in each plane there are four nodes, and each node is contained in six planes. The ( 2,3 )-curve $C$ must have 9 nodes. It has to contain six lines which correspond to the six planes that contain the node which is the center of projection. Since $C$ is the intersection of a smooth quadric and a cubic, it must consist of the six lines, and the cubic is in fact the union of three planes, each tangent to the quadric. Thus $C$ is the union of three pairs of lines, where each pair is the intersection of the quadric and a plane. Two lines on a plane have one intersection and any pair of lines intersects any other pair of lines in two points, thus we have nine nodes altogether, as we wanted.

The plane quintic $D$ consists of five lines that intersect one another in nodes, this gives the $\binom{5}{2}=10$ nodes. We do not need to do a stable reduction, so the normalization $N D$ is the disjoint union of five curves of genus zero, and the double cover $N \widetilde{D}$ is the disjoint union of ten curves of genus zero. (For the dual graph $\widetilde{\Gamma}$ of $\widetilde{D}$ see $[G w 05$, Figure 1].) Thus the intermediate Jacobian
does not have a compact part, and for dimension reasons it is

$$
\begin{equation*}
I J(X)=\left(\mathbb{C}^{*}\right)^{5} \tag{4.4.4}
\end{equation*}
$$

There is more degeneration data provided in [Gw05]; here we only wanted to show that the compact part is trivial.
