

What everyone already knows about groups.

(Dummit & Foote Chapters 1-9, approximately.)

- (1) Definitions. Language. Terminology, like ‘order of a group or element’, ‘exponent of a group’, ‘index of a subgroup’. Notation, like $|G|$, G/N , $[G : H]$, $[x, y]$. Easy syntactic results, like: the group axioms imply (i) $(x^{-1})^{-1} = x$ and (ii) $(xy)^{-1} = y^{-1}x^{-1}$.
- (2) Examples:
 - (a) \mathbb{Z} , \mathbb{Z}_n , S_n , A_n , D_n , D_∞ , Q_8 , $GL_n(\mathbb{F})$, $SL_n(\mathbb{F})$, $PSL_n(\mathbb{F})$, $O_n(\mathbb{F})$.
 - Know how to compute in these groups, so know modular arithmetic, cycle decomposition of permutations, matrix arithmetic.
 - (b) Groups of small order: know a complete list of groups of order < 16 .
- (3) H, S, P:
 - (a) Homomorphisms. Inner/outer automorphisms.
 - (b) Subgroups/normal subgroups. Subgroups of index 2 are normal.
 - (c) Quotient groups.
 - (d) Lattices of subgroups/normal subgroups.
 - (e) Left invariant equivalence relations on groups. Cosets. Double cosets.
 - (f) Characterization of products and of semidirect products.
- (4) Basic structure theorems:
 - (a) Cayley Representation Theorem.
 - (b) Noether’s Isomorphism Theorems. (3)
 - (c) Correspondence Theorem.
 - (d) Jordan-Hölder Theorem.
 - (e) Lagrange’s Theorem.
 - (f) Cauchy’s Theorem.
 - (g) Sylow’s Theorems.
- (5) Commutator theory:
 - (a) Abelianness.
 - (b) Centralizers.
 - (c) Nilpotence: center, ascending/descending central series.
 - (d) solvability: derived group/series.
- (6) Group actions:
 - (a) Equivalent definitions, terminology (G -set, orbit, transitive action, (semi)regular action, homomorphisms/automorphisms).
 - (b) Orbit-Stabilizer Theorem.
 - (c) Class equation.
 - (d) Structure Theorem.
 - (e) Conjugacy action on elements, subgroups. Conjugacy classes, normalizers. Conjugacy classes in S_n , A_n , $GL_n(\mathbb{F})$.
- (7) Abelian groups:
 - (a) Structure Theorem for f.g. abelian groups.
 - (b) Invariant factor form versus elementary divisor form.
- (8) Infinite groups:
 - (a) Free groups, reduced words.
 - (b) Presentations. Universal property of presentations.
 - (c) Coproducts of groups given by presentations.

Terminology for functions.

Let A and B be sets and let $f: A \rightarrow B$ be a function from A to B . There are sets and functions related to A, B and f that have special names.

- (1) The *image* of f is $\text{im}(f) = f[A] = \{b \in B : \exists a \in A(f(a) = b)\}$. The image of a subset $U \subseteq A$ is $f[U] = \{b \in B : \exists u \in U(f(u) = b)\}$.
- (2) The *preimage* or *inverse image* of a subset $V \subseteq B$ is $f^{-1}[V] = \{a \in A : f(a) \in V\}$.
- (3) The preimage of a singleton $\{b\}$ is written $f^{-1}(b)$ and sometimes called the *fiber* of f over b . The fiber $f^{-1}(f(a))$ containing the element a is sometimes written $[a]$.
- (4) The *kernel* of f is $\ker(f) = \{(a, a') \in A^2 : f(a) = f(a')\}$, which is an equivalence relation on A .
- (5) The *kernel class* of an element $a \in A$ is the same as the fiber $[a]$ that contains it. It is often written $a/\ker(f)$ to emphasize that it is a kernel class.
- (6) The *coimage* of f is the set

$$\text{coim}(f) = \{f^{-1}(b) : b \in \text{im}(f)\} = \{[a] : a \in A\} = A/\ker(f)$$

of all nonempty fibers.

- (7) The *natural map* is $\nu: A \rightarrow \text{coim}(f): a \mapsto [a]$. (More generally, for any equivalence relation E on A , the natural map is $\nu: A \rightarrow A/E: a \mapsto a/E$.)
- (8) The *inclusion map* is $\iota: \text{im}(f) \rightarrow B: b \mapsto b$. (More generally, for any subset S of B , the inclusion map is $\iota: S \rightarrow B: b \mapsto b$.)
- (9) The *induced map* is $\bar{f}: \text{coim}(f) \rightarrow \text{im}(f): [a] \mapsto f(a)$.

Some facts:

- (1) The natural map is *surjective*.
- (2) The inclusion map is *injective*.
- (3) The induced map is *bijective*.
- (4) $f = \iota \circ \bar{f} \circ \nu$. (This is the *canonical factorization* of f .)
