## Sums and averages of arithmetic functions (Ch. 3).

GOAL: given an arithmetic function  $f$ , to study the growth of sums like

$$(a) \sum_{n \leq x} f(n),$$

$$(b) \frac{1}{x} \sum_{n \leq x} f(n)$$

as  $x \rightarrow \infty$ .

Notes:

- 1) Always, (a) denotes the sum over  $n \in \mathbb{Z}^+$  with  $n \leq x$ .
- 2) (b) is a kind of average of the first  $[x]$  values of  $f$ .

Some terminology:

(1) "sufficiently large" means  $\geq a$ , for some  $a \in \mathbb{R}_+$ .

(2) Suppose  $f: \mathbb{R} \rightarrow \mathbb{C}$  and  $g: \mathbb{R} \rightarrow \mathbb{R}$ , with  $g(x) > 0$  for  $x$  suff. large. We write

$f(x) = O(g(x))$  (" $f(x)$  is big oh of  $g(x)$ ")

if  $f(x)/g(x)$  is bounded for  $x$  suff. large (equivalently,  $\exists M > 0$  such that  $|f(x)| \leq Mg(x)$  for  $x$  suff. large).

(3) For such  $f, g$  and  $h: \mathbb{R} \rightarrow \mathbb{C}$ , we write  $f(x) = h(x) + O(g(x))$  if  $f(x) - h(x) = O(g(x))$ .

(2)

(4) We write  $f(x) \sim g(x)$  (" $f(x)$  is asymptotic to  $g(x)$ ") if

$$\lim_{x \rightarrow \infty} \frac{f(x)}{g(x)} = 1.$$

### Examples

$$(i) x^2 = O(x^2)$$

$$(ii) x^2 + x = O(x^2)$$

$$(iii) x^2 + x = x^2 + O(x)$$

$$(iv) x^2 + x + 25 \sin(x) = x^2 + x + O(1)$$

$$(v) x^2 + x \sim x^2$$

(vi)

$$\sum_{p \leq x} 1 \sim \frac{x}{\log x} : \text{this is the } \underline{\text{Prime Number Theorem.}}$$

(we'll prove this later).

(vii) Harder result (we won't prove this) :

$$\sum_{p \leq x} 1 = \frac{x}{\log x} + O\left(\frac{x}{(\log x)^2}\right). \quad \text{"error term"}$$

A primary tool for deducing " $O()$ " and " $\sim$ " results for sums like (a) and (b) above is:

Theorem 3.1 : Euler summation formula, or ESF.

If  $f : [y, x] \rightarrow \mathbb{R}$  is continuously differentiable on  $[y, x]$ , and  $0 < y < x$ , then

$$\sum_{\substack{y < n \leq x \\ \uparrow}} f(n) = \int_y^x f(t) dt + \int_y^x (t - [t]) f'(t) dt$$

$$+ f(x)([x] - x) + f(y)([y] - y).$$

<, not ≤

Proof.

Denote the sum by  $S(f; y, x)$ , and note that

$$S(f; y, x) = \sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor} f(n).$$

Then

$$\int_y^x f(t) dt + \int_y^x (t - \lfloor t \rfloor) f'(\lfloor t \rfloor) dt$$

$$= \int_y^x f(t) dt + \underbrace{\int_y^x t f'(\lfloor t \rfloor) dt}_{\text{integrate by parts with } u=t, dv=f'(\lfloor t \rfloor) dt} - \int_y^x \lfloor t \rfloor f'(\lfloor t \rfloor) dt$$

← integrate by parts  
with  $u=t$ ,  $dv=f'(\lfloor t \rfloor) dt$

$$= \left[ \int_y^x f(t) dt + t f(t) \right]_y^x - \int_y^x f(t) dt - \int_y^x \lfloor t \rfloor f'(\lfloor t \rfloor) dt$$

$$= xf(x) - yf(y) - \int_y^x \lfloor t \rfloor f'(\lfloor t \rfloor) dt$$

$\downarrow$   
break up  
 $[y, x]$  into  
subintervals

$$= xf(x) - yf(y) - \int_y^{\lfloor y \rfloor + 1} \lfloor t \rfloor f'(\lfloor t \rfloor) dt - \int_{\lfloor x \rfloor}^x \lfloor t \rfloor f'(\lfloor t \rfloor) dt$$

$$- \sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor - 1} \int_n^{n+1} \lfloor t \rfloor f'(\lfloor t \rfloor) dt$$

$\downarrow$   
[ $t$ ] is constant  
on each given  
subinterval

$$= xf(x) - yf(y) - [\lfloor y \rfloor] \int_y^{\lfloor y \rfloor + 1} f'(\lfloor t \rfloor) dt$$

$$- [\lfloor x \rfloor] \int_{\lfloor x \rfloor}^x f'(\lfloor t \rfloor) dt - \sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor - 1} n \int_n^{n+1} f'(\lfloor t \rfloor) dt$$

$$= xf(x) - yf(y) - [\lfloor y \rfloor] (f(\lfloor y \rfloor + 1) - f(y))$$

$$- [\lfloor x \rfloor] (f(x) - f(\lfloor x \rfloor)) - \sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor - 1} (nf(n+1) - nf(n))$$

$\downarrow$   
make sum go  
to  $[x]$ ; then  
compensate

$$= xf(x) - yf(y) - [\lfloor y \rfloor] (f(\lfloor y \rfloor + 1) - f(y))$$

$$- [\lfloor x \rfloor] (f(x) - f(\lfloor x \rfloor)) + [\lfloor x \rfloor] f(\lfloor x \rfloor + 1) - [\lfloor x \rfloor] f(\lfloor x \rfloor)$$

$$-\sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor} (nf(n+1) - nf(n))$$

**add and subtract**

$$\downarrow$$

$$xf(x) - yf(y) - \lfloor y \rfloor (f(\lfloor y \rfloor + 1) - f(y))$$

$$- \lfloor x \rfloor f(x) + \lfloor x \rfloor f(\lfloor x \rfloor + 1) + S(f; y, x)$$

$$-\sum_{n=\lfloor y \rfloor + 1}^{\lfloor x \rfloor} (nf(n+1) - (n-1)f(n))$$

**the sum telescopes**

$$\downarrow$$

$$xf(x) - yf(y) - \lfloor y \rfloor (f(\lfloor y \rfloor + 1) - f(y))$$

$$- \lfloor x \rfloor f(x) + \cancel{\lfloor x \rfloor f(\lfloor x \rfloor + 1)} + S(f; y, x)$$

$$- \cancel{\lfloor x \rfloor f(\lfloor x \rfloor + 1)} + \cancel{\lfloor y \rfloor f(\lfloor y \rfloor + 1)}$$

$$= (x - \lfloor x \rfloor) f(x) - (y - \lfloor y \rfloor) f(y) + S(f; y, x),$$

as required.  $\square$

Note: sometimes, for integral  $y$  (e.g.  $y = 1$ ), we want to sum over  $[\lfloor y \rfloor, x]$  instead of  $(y, x]$ . This adds one more term to our sum; moreover, for such  $y$ ,  $\lfloor y \rfloor - y = 0$ . So ESF yields:

Corollary: ESF'. For  $y \in \mathbb{Z}_+$  and everything else as above,

$$\begin{aligned} \sum_{y \leq n \leq x} f(n) &= \int_y^x f(t) dt + \int_y^x (t - \lfloor t \rfloor) f'(t) dt \\ &\quad + f(x)(\lfloor x \rfloor - x) + f(y). \end{aligned}$$
