

Conditional probability (Chapter 8).

GOAL: to understand "the prob. of A given B," written  $P(A|B)$ , meaning "the prob. of A happening assuming B happened."

Part 1. A formula for  $P(A|B)$ .

Suppose we have a sample space  $S$  of equally likely outcomes.

We know that

$$P(A) = \frac{n(A)}{n(S)}. \quad (*)_0$$

To get  $P(A|B)$  from this, we have to:

(a) Replace  $n(S)$  by  $n(B)$ , since assuming B happened means only looking at outcomes in B. (That is, B becomes our new sample space.)

(b) Replace  $n(A)$  by  $n(AB)$  since, if we're assuming B happened, then whenever A happens, both A and B do.

SO:  $(*)_0$  gives

$$P(A|B) = \frac{n(AB)}{n(B)}. \quad (*)_1$$

Example 1.

Two fair dice are rolled. Define events A and B:

A: both dice lands on 6.

B: at least one die lands on 6.

Find  $P(A|B)$ .

Solution

If we write the outcomes as 11, 12, 13, ..., 66, then they are all equally likely.

Note that

$$B = \{61, 62, 63, 64, 65, 66, 56, 46, 36, 26, 16\}$$

and

$$AB = \{66\}.$$

So by  $(*)_1$

$$P(A|B) = \frac{n(AB)}{n(B)} = \frac{1}{11} \approx 0.0909 \\ = 9.09\%.$$

Note: experimentally, AB happened about 12.5% of the time B happened, not 9.09%. Why was our experimental proportion so high?

Possible answer: bias. If we were eager to stop as soon as we got our 5<sup>th</sup> (or 6<sup>th</sup>, or 7<sup>th</sup>, or...) 66, then we favored that outcome.

Let's go back to  $(*)_1$ . We'd like a formula only involving probabilities, not sizes of sets. To do this, multiply top and bottom of the right side of  $(*)_1$  by  $n(S)$ :

③

$$P(A|B) = \frac{n(AB)/n(S)}{n(B)/n(S)} = \frac{P(AB)}{P(B)}.$$

This formula:

$$P(A|B) = \frac{P(AB)}{P(B)} \quad (*_2)$$

is the formula for the conditional prob.  $P(A|B)$ .

We define  $P(A|B)$  this way even when outcomes aren't equally likely.

Example 2.

A fair coin, and an unfair coin, with  $P(\text{heads}) = 1/3$ , are tossed. Given that at least one coin lands heads, what is  $P(\text{at least one coin lands tails})$ ?

Solution. Our events are

$A$ : at least one coin lands tails

$B$ : at least one coin lands heads.

By  $(*_2)$ ,  $P(A|B) = P(AB)/P(B)$ .

Now

$$\begin{aligned} P(AB) &= P(\text{fair coin lands heads and unfair lands tails}) \\ &\quad + P(\text{fair coin lands tails and unfair lands heads}) \\ &= \frac{1}{2} \cdot \frac{2}{3} + \frac{1}{2} \cdot \frac{1}{3} = \frac{2}{6} + \frac{1}{6} = \frac{3}{6} = \frac{1}{2}, \end{aligned}$$

while

$$\begin{aligned} P(B) &= P(\text{fair is heads, unfair lands tails}) \\ &\quad + P(\text{fair is tails, unfair is heads}) \end{aligned}$$

③

+  $P(\text{both are heads})$

$$= \frac{1}{2} \cdot \frac{2}{3} + \frac{1}{2} \cdot \frac{1}{3} + \frac{1}{2} \cdot \frac{1}{3} = \frac{4}{6} = \frac{2}{3}.$$

So

$$P(A|B) = \frac{P(AB)}{P(B)} = \frac{\frac{1}{2}}{\frac{2}{3}} = \frac{1}{2} \cdot \frac{3}{2} = \frac{3}{4} = 75\%.$$

Question: what would  $P(A|B)$  be if both coins are fair??
